Table 21 lists various complications known to occur with various inhalants. The DSM-5 lists a number of inhalant-related disorders: inhalant use disorder (mild, moderate, severe), inhalant intoxication, other inhalant-induced disorders, and unspecified inhalant related disorders [23].

Most abusers of inhalants discontinue these drugs by stopping substance abuse in general or moving on to other drugs. Management of those who become chronic inhalant abusers is difficult, often being hindered by their many, varied behavioral and social problems. Research on management is focusing on inhalant effects on dopaminergic, glutamatergic and GABAergic systems [61]. Unfortunately death from volatile substance misuse may occur as seen, for example, with difluoroethane can occur.

BARBITURATES

These are CNS depressants that are classified as sedative-hypnotic drugs. They act on the CNS by enhancing the neuroinhibitory action of gamma-aminobutyric acid (GABA) and

producing relief from anxiety and sedation. They are classified as ultra-short acting (thiopental), short acting (pentobarbital [yellow jackets], secobarbital [reds]), and long acting (phenobarbital). The short acting barbiturates have a higher potential for abuse and are more lipid soluble than the long acting formulations.

They can become addicting in 1 to 2 months and are deadly in high doses or when combined with opioids or alcohol. Abuse of these drugs leads to physical addiction, abstinence, and discontinuation syndrome, similar to that noted with alcohol abuse. The DSM-5 lists a number of “sedative, hypnotic, or anxiolytic”-related disorders: sedative, hypnotic, or anxiolytic use disorder (mild, moderate, severe); sedative, hypnotic, or anxiolytic intoxication; sedative, hypnotic, or anxiolytic withdrawal; other sedative, hypnotic, or anxiolytic -induced disorders; and unspecified sedative, hypnotic, or anxiolytic related disorders [23].

Barbiturates are detoxified in the liver and/or excreted unchanged in the urine. Symptoms of acute use and overdose are similar to those of alcohol and include euphoria, slurred speech, lethargy, miosis, and ataxia. Overdosing leads to low blood pressure, bullous dermatological lesions, respiratory depression, coma, and death. It is not commonly abused at current times and involves less than 3% of high school students. This reduced abuse probably reflects infrequent clinician prescription of these drugs, reduced availability on the streets, and the availability of many other illicit drugs. Barbiturates should usually not be prescribed to adolescents and then, only with extreme caution.

CONCLUSION

Substance abuse continues to be a widespread and very serious phenomenon for our adolescents and young adults in the United States and around the globe. Many factors draw our youth into these deadly drugs, leading to many acute and chronic sequelae, ranging from addiction to death. Youth must be clearly and carefully taught that drug use and abuse comes with considerable complications for their current and future life. They also must be taught that there is no scientific evidence that smoking cannabis is safe nor is medically beneficial. They must also become aware of the dangers of the designer drugs that are being produced in greater amounts.

Clinicians must join with other members of society to educate our patients to the many deadly and dangerous drugs of abuse that are available and work with society (including governments) to reduce the availability of drugs [62-78]. The human instinct for pleasure at any cost must be tempered with education and direction from clinicians. Management of those addicted to drugs is a complex, often discouraging process. Psychosocial and behavioral therapies are important that involve a variety of health specialists. Group, family, and individual therapy all have a place in management and many need intensive treatment in drug abuse programs.

Chapter 512

FROM THE BATTERED CHILD SYNDROME TO ABUSE AND MALTREATMENT: A PUBLIC HEALTH VIEW

Vincent J. Palusci*, MD, MS and Margaret T. McHugh, MD, MPH

Department of Pediatrics, New York University School of Medicine,
Frances L Loeb Child Protection and Development Center, New York, New York, USA

ABSTRACT

This review serves as a primer for professionals who, regardless of their individual interests and fields of expertise, can improve the growth and development of children by understanding, responding to, and preventing abuse and maltreatment in the child and adolescent. It provides an overview of the types, medical assessment, and treatment of children with potential abuse and maltreatment, and the preventive community services that can be provided to help their families. It outlines areas of current research and highlights issues that still need to be addressed. The experience of the past fifty years has established a solid foundation in preparation for the work that child health clinicians still need to do in the field of child abuse medicine.

Keywords: childhood, adolescence, abuse, neglect, maltreatment, public health

INTRODUCTION

In the fifty years since the publication of C Henry Kempe's (1922-1984) landmark article, "The battered child syndrome" [1], the subject of child maltreatment has become a universal topic, not restricted to one community or to one type of provider. As the field has grown, professionals have had to broaden their intellectual and personal perspectives to not only identify maltreatment but also to provide interventions to prevent further abuse. The current goal of professionals dedicated to this field is primary prevention, to insure that child abuse, like many infectious diseases of the past century, will be eradicated in the near future.

* Corresponding Author's Email: Vincent.palusci@nyumc.org.

While each state in the United States (US) defines child maltreatment in its child welfare and criminal statutes, broad definitions have been developed for the Child Abuse Prevention and Treatment Act [2] and by the World Health Organization (see Table 1).

While child abuse overall pertains to the variety of acts committed or omitted by parents or caretakers for children, the quality of the parent-child relationship and nurturing is often left out of state laws. In the broader sense, the WHO [3] adds qualitative definition and context to this relationship and the more broad nature of caring for children.

Table 1. World Health Organization definitions*

Child Abuse - Child abuse or maltreatment constitutes all forms of physical and/or emotional ill-treatment, sexual abuse, neglect or negligent treatment or commercial or other exploitation, resulting in actual or potential harm to the child's health, survival, development, or dignity in the context of a relationship of responsibility, trust or power.
<i>Physical Abuse</i> - Physical Abuse of a child is that which results in actual or potential physical harm from an interaction or lack of an interaction, which is reasonably within the control of a parent or person in a position of responsibility, power or trust. There may be a single or repeated incidents.
Emotional Abuse - Emotional abuse includes the failure to provide a developmentally appropriate, supportive environment, including the availability of a primary attachment figure, so that the child can establish a stable and full range of emotional and social competencies commensurate with her or his personal potentials and in the context of the society in which the child dwells. There may also be acts towards the child that cause or have a high probability of causing harm to the child's health or physical, mental, spiritual, moral or social development. These acts must be reasonably within the control of a parent or person in a position of responsibility, power or trust. Acts include restriction of movement, patterns of belittling, denigrating, scapegoating, threatening, scaring, discriminating, ridiculing or other non-physical forms of hostile or rejecting treatment.
Neglect and negligent treatment - Neglect is the failure to provide for the development of the child in all spheres: health, education, emotional development, nutrition, shelter and safe living conditions, in the context of resources reasonably available to the family or caretakers and causes or has a high probability of causing harm to the child's health or physical, mental, spiritual, moral or social development. This includes the failure to properly supervise and protect children from harm as much as is feasible.
Sexual abuse - Child sexual abuse is the involvement of a child in sexual activity that he or she does not fully comprehend or is unable to give informed consent to, or that violates the laws or social taboos of society. Child sexual abuse is evidenced by this activity between a child and an adult or another child who by age or development is in a relationship of responsibility, trust or power, the activity being intended to gratify or satisfy the needs of the other person. This may include but is not limited to: The inducement or coercion of a child to engage in any unlawful activity The exploitative use of a child in prostitution or other unlawful sexual practices The exploitative use of children in pornographic performances and materials
Exploitation - Commercial or other exploitation of a child refers to the use of the child in work or other activities for the benefit of others. This includes, but is not limited to, child labour and child prostitution. These activities are to the detriment of the child's physical or mental health, education, or spiritual, moral or social-emotional development.

*World Health Organization (WHO). (1999). *Report of the consultation on child abuse prevention*. Geneva, Switzerland: Author.

In the effort to allow diagnostic coding for physicians in medical systems and for medical examiners and coroners for state public health statutes, the International Classification of Disease Codes have been developed applicable to child abuse and neglect. ICD-9 lists individual types as well as external modifiers related to perpetrator relationship ("E codes"). A revised set of codes (ICD-10) is increasingly being used [4], and comparisons of the two systems are listed in Table 2.

Table 2. International classification of disease codes applicable to child abuse (ICD-9)

<i>ICD-9</i>	<i>ICD-10</i>
995.50 Child abuse, unspecified	T74.92 Unspecified child maltreatment
995.51 Child emotional/psychological abuse	T74.32 Child psychological abuse
995.52 Child neglect (nutritional) Use additional code to identify intent of neglect (E904.0,E968.4)	T74.02 Child neglect or abandonment
995.53 Child sexual abuse	T74.22 Child sexual abuse
995.54 Child physical abuse Battered baby or child syndrome <i>Excludes: Shaken infant syndrome (995.55)</i>	T74.12 Child physical abuse
995.55 Shaken infant syndrome Use additional code(s) to identify any associated injuries	T74.4 Shaken infant syndrome
E967 Perpetrator of child and adult abuse	
E967.0 By father, stepfather, or boyfriend Male partner of child's parent or guardian	
E967.2 By mother, stepmother, or girlfriend Female partner of child's parent or guardian	
E967.3 By spouse or partner Abuse of spouse or partner by ex-spouse or ex-partner	
E967.4 By child	
E967.5 By sibling	
E967.6 By grandparent	
E967.7 By other relative	
E967.8 By non-related caregiver	
E967.9 By unspecified person	

EPIDEMIOLOGY

The victimization of children through abuse and neglect remains an all too common occurrence. In the United States, 1-2 per 1,000 children are victimized by physical abuse each year, and young children and infants have the highest rates. Maltreated children suffer from a variety of behavior problems and mental disorders in addition to physical injuries [5, 6]. The Adverse Childhood Experiences study has noted the powerful relationship between adverse childhood experiences and several conditions of adulthood, including risk of suicide, alcoholism, depression, illicit drug use, and other lifestyle changes [7-9]. While the exact pathways are still being explored, childhood abuse is thought to affect adult health by putting people at risk for depression and post-traumatic stress disorders, difficulties in relationships, and negative beliefs and attitudes towards others through mechanisms of toxic stress [10-11].

Two large administrative sources provide information about the U.S. annual incidence of child maltreatment, the National Child Abuse and Neglect Data System (NCANDS) and the National Incidence Studies of child abuse and neglect (NIS). NCANDS contains aggregate and case-level data on child abuse reports received by state Child Protective Service (CPS) agencies, and almost all US states and territories provide information annually about the outcomes of child abuse reports, types of maltreatment, child and family factors and services

being provided [12]. National estimates of the overall numbers of victims (substantiated or indicated CPS reports) as well as victims identified with physical and sexual abuse show decline over the 20+ years of nationally collected data in NCANDS (see Figure 1), following similar trends in other national crime statistics [12].

In contrast, NIS samples sentinel counties to identify maltreatment under two standards: the harm standard (relatively stringent in that it generally requires that an act or omission result in demonstrable harm in order to be classified as abuse or neglect) and the endangerment standard (which allows children who were not yet harmed by maltreatment to be counted if the CM was confirmed by CPS or identified as endangerment by professionals outside CPS, either by their parents or other adults) [13]. The Fourth National Incidence Study of Child Abuse and Neglect (NIS-4) also shows an overall decrease in the incidence of maltreatment since the NIS-3, as well as decreases in some specific maltreatment categories and increases in others. Using the stringent Harm Standard definition, more than 1.25 million children (an estimated 1,256,600 children) experienced maltreatment during the NIS-4 study year (2005–2006). A large percentage (44%) or an estimated total of 553,300 were abused, and most of these abused children experienced physical abuse (58%).

MN = Medical Neglect; NEG = Neglect; PA = Physical Abuse; PM = Psychological Maltreatment; SA = Sexual Abuse [6].

Figure 1. United States child maltreatment victims (NCANDS), 1990-2011.

Smaller independent samples offer additional information. In the Carolinas, the incidence of harsh physical discipline was found to be 4.3% of respondents (with 2.4% shaking infants), and a retrospective prevalence survey, reported 24% of adolescents being physically assaulted [14, 15]. The range of incidence rates of abusive head trauma (AHT) has been found to be 27.5-32.2 per 100,000 in a large U.S. inpatient database, with an estimates rising during 1997 to 2009 [16]. Lane et al. [17] noted hospital discharge rates of 1.8 per 100k, with 25% of head trauma in infants being abusive.

Unlike the reported incidence of sexual abuse, in which it has been suggested that at least some of the decrease is real, it is not clear if or why physical abuse rates have actually declined [18, 19]. While economic indicators improved in the 1990's during the decline, the number of cases continued to fall in NCANDS in 2008-2011 during an economic recession [20]. This may indicate that states are changing how they count child maltreatment fatalities or how they are delivering that information to NCANDS as could occur with differential response systems [12]. Further studies are needed to ascertain whether the number of physical abuse cases is continuing to decline and the causes why this is occurring. A number of smaller samples have suggested a rise in more serious child physical abuse associated with the U.S. economic recession.

It has been noted that the abusive head trauma rate increased from 8.9 to 14.7 per 100,000 and a doubling from 0.7 to 1.4 per month during the recession [20]. Wood et al. [21] noted increasing rates of children admitted to hospitals for physical abuse over 10 years 2000-2009, rising from 0.8 to 3% annually. Rates of physical abuse reportedly also fell in the UK during 1974 to 2008 [22]. Neglect continues to affect more than 50% of those children reported to child protective services, and the parents of young neglected children were less likely to have completed high school, had more preschool children and had less parenting skills and social support [23]. Disabled children also have increased risk [24]. When broken down by age and type of child maltreatment, it is apparent that most CM occurs in very young children and most CM is neglect (see Figure 2). This pattern continues with older children, but the number falls dramatically. For sexual abuse, older children are more affected. Medical neglect, in contrast, affects mostly infants.

Similar relationships hold as a proportion of the total number of victims identified in NCANDS. Younger children are the highest proportion for all CM types, except sexual abuse (see Figure 3).

MN = Medical Neglect; NEG = Neglect; PA = Physical Abuse; PM = Psychological Maltreatment; SA = Sexual Abuse [6].

Figure 2. Victims by age and maltreatment type, NCANDS 2011 [12].

MN = Medical Neglect; NEG = Neglect; PA = Physical Abuse; PM = Psychological Maltreatment; SA = Sexual Abuse [6].

Figure 3. Victims by age as a percentage of child maltreatment types, NCANDS 2011 [20].

Although the focus of concern about maltreatment is usually the younger child, statistics show that 30 to 50% of all reported cases involve adolescents [12]. In New York State in 1985, for example, there were 84,119 child maltreatment reports with substantiation rate of 35%. Within the adolescent reports, 19% were for physical abuse, 42.4% for sexual abuse, and the remainder for neglect [25]. In 2002, there were 153,603 reports of child maltreatment in New York with a substantiation rate of 31.1%. Of those, children from ages 10-17 years accounted for 47.9% (21,727 children) of the cases. Almost half (47%) of children entering foster care were over 10 years of age, and approximately 75% remained in care for longer than one year. In the same year in New York City, there were 10,922 children ages 10 to 17 years placed in foster care. Alarming, 15% of those in foster care were adolescents who had been in the system more than one year. These child maltreatment cases can only reflect those that come to the attention of the child protection system. Based on other sources of information regarding adolescent behaviors, maltreatment is given as a comorbid factor in a spectrum of adolescent problems, such as substance abuse, truancy, runaways and psychiatric disorders [26-28].

While there are varying schools of thought on the origins of maltreatment, most theories of child maltreatment recognize that the root causes can be divided into four principal systems: (1) the child, (2) the family, (3) the community, and (4) society. While children are certainly not responsible for the abuse inflicted upon them, there are certain characteristics that have been found to increase the risk for maltreatment. Children with disabilities or mental retardation, for example, are significantly more likely to be abused [24]. Evidence also suggests that age and gender are predictive of maltreatment risk. Younger children are more likely to be neglected, while the risk for sexual abuse increases with age. Female children and adolescents are significantly more likely than males to suffer sexual abuse.

Several factors have been associated with physical abuse. Unlike previous NIS cycles, NIS-4 found strong and pervasive race differences in the incidence of maltreatment with rates of maltreatment for Black children significantly higher than those for White and Hispanic

children. Under the Harm Standard, children with confirmed disabilities had significantly lower rates of physical abuse and of moderate harm from maltreatment, but they had significantly higher rates of emotional neglect and of serious injury or harm [13]. NIS-4 also confirmed findings from other studies which associated increased physical abuse in poor, larger, unemployed families, and one parent and an unrelated caregiver present. Zhou, Hallisey, & Freymann [29] found that infant maltreatment can best be predicted when there are young mothers less than 20 years, who are unmarried, with inadequate prenatal care, are poor, who smoke during the pregnancy, or when there are three or more siblings. In an NCANDS sample, parent emotional problems, alcohol abuse and other family violence were found to be associated with the recurrence of physical abuse before age three years [30].

Community and social factors also play a role in child maltreatment. Poverty, for example, has been linked with maltreatment, particularly neglect, in each of the national incidence studies [13], and has been associated with child neglect, a strong predictor of substantiated child maltreatment [31]. The following factors have been linked to child maltreatment: fewer friends in their social support networks, less contact with friends, and lower ratings of quality support received from friends [32]. Violence and unemployment are other community-level variables that have been found to be associated with child maltreatment.

Perhaps the least understood and studied level of child maltreatment is that of society. Ecological theories postulate that factors such as the narrow legal definitions of child maltreatment, the social acceptance of violence (as evidenced by video games, television and films, and music lyrics), and political or religious views that value noninterference in families above all may be associated with child maltreatment [6].

Clinical Features

Several health effects of child maltreatment have been identified. While there is considerable overlap, specific health effects and injuries are often related to a major subtype of child abuse, and the medical diagnostic evaluation varies with the type of child maltreatment and the injuries of concern (see Table 3).

Physical Abuse

The most common injury from physical abuse affects the skin by bruising or burning. Recognition and documentation of bruises, burns and other skin lesions requires complete undressing of the child and comprehensive physical examination. Skin lesions should describe location, size, color, depth, and integrity of the epidermis and may be documented using notes, hand-drawn diagrams or photographs; law enforcement and child protection workers often have resources to assure high quality photo documentation. Even if photographs are taken, the pediatrician should also contemporaneously document skin injuries identified [33]. Additionally, specific statements by the family and child should also be copied verbatim in the medical chart for potential use later in the legal system.

Table 3. Medical diagnostic evaluation in child victimization emphasizing identification of cause and sequelae of physical injury

<i>History- Questions asked by healthcare professionals of the child and caretakers during medical encounter</i>
Chief Complaint (Why are you here today?)
History of Present Illness Circumstances surrounding injury Physical symptoms such as pain, bleeding, sensory problems, etc. Events leading to seeking medical care Timing
Prior medical treatments, surgery, medications, hospitalizations, mental health services
Prior evaluations for victimization
Chronic medical conditions, particularly bleeding, neurologic, metabolic, growth disorders
Immunizations received
Known allergies
Psychosocial history (caretakers, school attendance, housing, income, family structure)
<i>Physical Examination- done by the physician, nurse, or other practitioner based on history</i> Vital signs (pulse, respiration rate, height, weight, head circumference, Glasgow Coma Scale, pain scale) Skin (bruising, burns, pattern marks, contusions, tenderness) Head (presence of skin swelling, bruising, skull deformity, fontanelles) Eyes (pupillary response, sclera, retina, periorbital tissues) Ears (earlobes, canals, tympanic membranes) Nose (bleeding, nares, deformity) Mouth, throat (condition of teeth, tonsils, pharynx, frenula) Neck (flexibility, lymph glands, thyroid) Chest (rib deformities, air movement and congestion, tenderness) Heart (heart sounds, rhythm) Abdomen (tenderness, organ swelling, bowel sounds) Genitals (penis, scrotum, testes, urethra in males; labia, hymen, urethra, vagina in females) Anorectal (perineum, internal and external anal sphincters, rugal folds, tone) Extremities (movement, tenderness, swelling, joint involvement, pulses, ambulation) Neurological (alertness, reflexes, muscular strength and tone, cranial nerves, sensation)
<i>Laboratory – Tests performed as indicated by history and physical findings</i> Complete blood count (white and red blood cells, hematocrit, platelet counts) Coagulation studies (prothrombin, partial thromboplastin times, fibrinogen, platelet function) Blood chemistries, liver function tests X-rays of affected areas or skeletal survey of all bones for children less than three years Computer-assisted tomography (CT) scan of brain or other affected part Magnetic Resonance Imaging (MRI) of head or other affected part Specialized metabolic tests (collagen, organic and amino acids, others) Microbiologic cultures and tests for sexually transmitted infections Collection of forensic trace specimens (less than 72 hours after contact) Pregnancy testing (depending on sexual development and potential contact)
Diagnosis and Treatment- Identification of disease or sequelae of trauma Hospitalization for further diagnostic assessment or treatment (based on severity of illness/injury and/or need for surgical or supportive care) Reassurance and emotional support Referral for ongoing medical and mental health treatment CPS reporting and provision for immediate safety needs and protection

In the case of bruising, standard coagulation tests should be ordered to objectively assess platelet count and function as well as coagulation factors. Any skin lesion beyond temporary reddening should be considered as potential physical abuse when (1) the injury is inflicted and non-accidental, (2) the pattern of injury fits biomechanical models of abusive trauma, (3) the pattern corresponds to infliction with an instrument that would not occur through play or in the environment, (4) the history provided is not in keeping with the child's development, or (5) the history does not explain the injury [33].

The aging of bruises in children has received considerable attention and current guidelines are severely limited in their ability to precisely time when an injury occurred. Pattern, depth (degree), and healing of burns helps in determining their specificity for maltreatment. Developmental and other considerations need to be entertained as there are a host of potential confounders or 'mimics' which need to be reviewed when coming to a diagnosis. Some children as young as 10 months of age, for example, have been shown to have the developmental capability to climb into the bath, suggesting that nonspecific burn patterns could be attributed to actions by the child rather than the parent in some cases [34].

The distribution of lesions can be a critical factor in determining if a child has been abused. Certain sites are highly correlated with abuse, such as buttocks, the lower back, the posterior aspects of the extremities and the ears [35]. Bruising at other sites, such as the bony prominences of the forehead, the elbows and lower legs, are consistent with the normal childhood trauma seen in mobile children. Sugar et al. [36] noted "those who don't bruise rarely bruise," signaling we should be concerned when non-walking infants or motor delayed children have bruising. Inflicted bruising may have clear patterns or may be non-specific.

When an object is used, the pattern of the injury may clearly show the outline of the object. Another form of patterned bruising comes from biting. A careful inspection and measurement of the lesion can determine if a bite is human or animal, adult or child, or self-inflicted. Since the most common skin manifestation of physical abuse is multiple bruises in different stages of healing, it is imperative to use a diagram and appropriate imaging to document the color, distribution and pattern of these injuries. A burn is the destruction of skin and underlying tissue caused by the application of a physical agent. These agents may be chemicals, heat, cold, or electrical in nature. Since the spectrum of burns can range from a simple isolated injury to the involvement of major portions of the child's body, the clinician should assess the type of agent, the distribution and extent of the burn, and the history given of how the burn occurred [37]. Many burns in childhood are accidental but are also the result of poor judgment or the failure of the caretaker to provide adequate supervision. Here, as in other forms of abuse, the developmental age and the size of the child are very important. Inflicted burns often have very specific patterns such as those seen with immersion or dunking. Burns may result from splash, immersion, or contact with a heated instrument or utensil, a flame, a chemical/caustic agent or an electrical source.

Accidental burns/scalds commonly involve hot liquids in contact with a child's face, neck, and upper chest [38]. If a child pulls down a cup of hot water, this will produce a different pattern than if he had pulled a cup of thick liquid. The action may be modified by the height from which the hot liquid fell, the vehicle that contained the hot substance, and the child's size. Immersion burns present with distinctive patterns that result from placing the child in hot water. The patterns include stocking/glove burns that are symmetrical burns of the extremities. Forced immersion of the child in a tub can produce a burn pattern with well-demarcated lesions and little or no evidence of splash.

Contact burns can present with identifiable object patterns such as an iron or a cigarette lighter. A child can easily have contact with the iron left on the floor or by pulling the cord. Other sources of contact burns are room heaters, hair curling irons, electric cooking utensils, and radiators which can each produce distinctive lesions. Lit cigarettes can produce lesions that can be difficult to distinguish from chicken pox or impetigo given the similarity of the size and shape.

A variety of diagnostic issues await further study. As the Institute of Medicine [6] pointed out, there is a great deal of additional data needed by clinicians on the frontlines to assist in determining which children need evaluation for abuse, when subspecialists should be called, and what tests should be done. There are still issues on how to fund training for physicians to recognize and report abusive bruises and how to best train case workers, social workers and other investigators about medical issues. More research is needed to study innovative systems-level changes that may address challenges associated with decision making on medical issues by frontline workers.

Acute fractures may be clinically apparent as soft tissue swelling over a fracture site, a deformity of the involved limb, or as a decrease in movement with or without external bruising. Infants may present with irritability and/or not using an affected limb. Healing fractures may sometimes be identified as palpable lesions consistent with callus formation, especially over the ribs [39]. The absence of swelling or bruises near a fracture site is not uncommon in fractures of the extremities and ribs. A case series of 703 consecutive skeletal series reported 11% fractures, with higher rates in infants less than 6 months old, apparent life threatening events, seizures and abusive head trauma. 79% had healing fractures seen [40]. One study reported that when skeletal surveys were done, 23% identified additional fractures, 10% in the hands, feet or spine and follow-up x-rays in 1-2 weeks have been found to identify additional fractures in 8.5% of children [41].

There is no fracture type that is pathognomonic for abuse, and all fracture types can potentially result from inflicted injury. The diagnosis of inflicted fracture must be made through careful correlation of the history provided by the caregiver with the child's developmental level and physical and radiographic findings. Classic metaphyseal lesions, rib fractures (particularly posteriorly), scapular fractures, vertebral spinous process fractures, and sternal fractures all have a high specificity for abuse [42]. Common, nonspecific injuries include subperiosteal new bone formation, clavicular fractures, diaphyseal fractures of long bones, and linear skull fractures. There are some fracture types and findings of intermediate specificity that are concerning but may be accidental if a clearly plausible mechanism is provided. This group includes multiple fractures (particularly when bilateral), fractures of different ages, epiphyseal separation, digital fractures, vertebral body fractures and subluxations, and complex skull fractures.

The age of fractures can be helpful in assessing the plausibility of the history, and multiple fractures of different ages raise the suspicion of abuse. Fracture healing manifests as periosteal reaction, also called callus, which is radiographically apparent after 10–14 days, and can be seen earlier in infants [43, 44]. Subperiosteal new bone formation can be a normal finding in infants under 6 months of age when it is found along the shafts of long bones and is symmetrical on both sides of the body. Skull fractures cannot be dated with accuracy, however, when non-accidental trauma is suspected, appropriate skeletal studies should be done as outlined by the American College of Radiology [45] and the American Academy of Pediatrics Section on Radiology [46].

Skeletal survey is the standard diagnostic investigation when there is concern for physical abuse of infants and toddlers under two years old [46]. It includes antero-posterior (AP) views of the extremities including feet, with the exception of the hands which are imaged in the posterior-anterior view; AP and lateral skull; AP and lateral views of the thorax and oblique ribs; AP pelvis; and lateral views of the spine. Radiologic evaluation is necessary to assess both the fracture itself and overall status of the bony skeleton to identify any metabolic/genetic process that might produce bone fragility. A discussion of the various metabolic bone diseases associated with fractures is beyond the scope of this chapter, and a pediatric radiologist should be utilized since familiarity with the presentation of growth variables in the pediatric patient is very important in determining if the findings are consistent with non-accidental trauma or other explanations.

Several areas of continuing medical research include the delineation of the diagnosis, pathophysiology and injury mechanics of fractures, head trauma and other abuse injuries. Further research is indicated, and physicians should appropriately search and test for alternate explanations while appropriately weighting the strong available evidence to ensure that a child remains protected from harm. CT, for example has been suggested to be a more sensitive test for rib fractures, yet the increased radiation exposure may not warrant it for screening [47]. While it has been noted that vitamin D deficiency does not predispose to fracture in the absence of clinical rickets [48, 49], additional studies regarding the quantitative effects of such deficiencies could be helpful.

The leading cause of abusive mortality and morbidity is inflicted traumatic brain injury [50]. With mortality rates of 10–50% and more than 90% of survivors having significant developmental sequelae, physical abuse to the head has been noted to have patterns of injuries that are distinct from accidental or medical causes. At least 1,400 cases of fatal abusive head trauma occur annually in the United States, and there is growing sophistication in our ability to differentiate these fatalities from those from non-abusive causes. Prior to 1974, the presence of subdural hematomas in infants who had no apparent history or evidence of trauma was given the diagnosis of “idiopathic subdural hematoma of infancy”. With the publication of the article by Caffey in 1974 based on interviews of caretakers, this entity became known as the “Shaken Baby Syndrome” and later the “Shaken Baby/Impact Syndrome” as the awareness of this clinical entity grew and applied to related clinical situations [51]. New diagnostic technologies developed in the last century, from radiographs to sophisticated computer-assisted imaging techniques, have proved invaluable in visualizing internal bleeding and injury.

The mechanism for the injury has been described as the violent shaking of an infant resulting in the movement of the brain within the skull and related hemorrhage within the eye and optic nerve. Subdural bleeding is thought to be caused by the disruption of the bridging veins within the subdural space. Rib fractures are attributed to the compression of the chest by the caretaker as the infant was shaken. This mechanism of injury is consistent with the histories given by providers over the years in which the caretaker sought to silence the crying infant by grabbing the child around the thorax and shaking the child until the child stopped crying. Alternative terms for this clinical entity are now being used, including Abusive Head Trauma or Non-Accidental Head Injury, to indicate head trauma without reference to the mode of injury. Infants and children under 3 years with interhemispheric subdural hemorrhage were found to have a greater than 99% probability of intentional trauma, and predictive values of a variety of injuries have been calculated [52]. However, a pattern of

head crush injuries increasingly seen after TV falls reminds us that these findings are not always pathognomonic for abusive head trauma [53]. Whether external hydrocephalus or “benign extra-axial fluid of infancy” predisposes to subdural bleeding is still not clear. The potential contribution of birth and other factors such as maternal anti-Ro antibodies is also provocative [54]. Newer imaging modalities, such as diffusion tensor imaging, offer valuable ways to detect the effects of AHT, but further studies are needed to help us integrate them into clinical practice [55-57].

Approximately 4%-6% of abused children have ocular findings. Any ocular injury can be the result of abuse, and all forms of abuse may have ophthalmic manifestations [58]. The incidence of retinal hemorrhages (RH) in shaken-baby syndrome (SBS) is 85%, but higher in children who have died versus unimpaired survivors. There is an association between severity of brain injury and RH severity, and RH can rarely occur without intracranial hemorrhage or cerebral edema [59]. Approximately two-thirds of victims have RHs that are too numerous to count and are multilayered. These RHs extend out to the retinal periphery, with no particular anatomic pattern, and cover the majority of the retinal surface. Macular retinoschisis also indicates trauma. RH cannot be dated with precision. Massive numbers of superficial or small-dot hemorrhages can resolve within 24 hours.

There is some evidence that mild increases of RH, or the appearance of RH not previously present, can occur early during hospitalization in very ill children, which underscores the need for prompt ophthalmology consultation and retinal evaluation [60]. A small number of infants have been noted to have RH after birth that resolve within two weeks. It is also known that RHs in the posterior pole are associated with non-abusive causes. The overwhelming body of literature supports a conclusion that severe hemorrhagic retinopathy in otherwise previously well children without obvious history to the contrary (e.g., head crush or high velocity impact) suggests that the child has been submitted to repetitive acceleration-deceleration trauma with or without head impact [58].

There is a growing body of knowledge about abusive abdominal and chest trauma which are often ‘silent’ injuries with potentially devastating consequences. Abdominal injuries are the second leading cause of death after abusive head trauma but are difficult to assess given their occult nature, relative lack of bruising, and potential for significant delay in symptoms. Even with a history of a severe blow to the abdomen, bruising of the skin is often not seen. Examination may reveal guarding and change/loss of bowel sounds. Lab studies must address injuries to all the abdominal organs including the kidneys. CT scans of the abdomen are very useful in determining the extent of these injuries when the physical findings are diffuse and non-specific. Direct blows to the abdomen such as a punch, kick or use of an object can injure both solid and hollow organs which are both impacted and compressed against the vertebral column [61].

One study demonstrated that solid organ injuries were most common in both accidental and inflicted trauma. Hollow viscus injuries, alone or in combination with solid organ damage, were more common in cases of inflicted injuries [62]. Recent studies suggest that abdominal CT imaging and liver function and pancreatic testing should be carried out in all abusive head trauma victims to identify occult abdominal trauma given that 25% or more of even fatal abdominal trauma cases can have few or no visible external bruises [61]. Inflicted chest injuries in children are uncommon as a single episode of trauma but are often seen in conjunction with other non-accidental injuries such as inflicted head trauma with compression fractures of the ribs. Direct blows to the chest wall rarely present with damage to the heart or

the thoracic duct [63]. Many of these injuries are fatal and only identified at post mortem exam. Cardiac troponins have been found to be increased after abusive chest trauma, and the time course and screening evaluation of serologic markers for abusive abdominal trauma need further study [64].

Sexual Abuse

Sexual abuse has been defined as sexual contacts or exploitation of children by adults, which cannot be consented to, and which violate social laws or taboos. Sexual assault is a comprehensive term encompassing several types of forced sexual activity, while the term molestation means non-coital sexual activity between a child and an adolescent or adult. Rape is defined as forced sexual intercourse with vaginal, oral or anal penetration by the offender. Acquaintance or “date rape” apply when the assailant and victim know each other. Statutory rape involves sexual penetration of a minor by an adult as defined in varying state laws, regardless of assent [65].

A prime injury of sexual abuse is emotional. While most young children with proven sexual abuse have few physical injuries, patterns of anogenital injury and sexually transmitted diseases have been identified [66]. Several large case series have been published highlighting the normalcy of most examinations [66-68]. Assessing sexual abuse requires detailed knowledge of anogenital anatomy and sexually transmitted infections (STIs) in children, both of which have important differences from adults, and specialized skills and examination techniques have had to be developed [69, 70]. It has become apparent that most physicians have little knowledge about prepubertal genital anatomy and cannot identify key landmarks. This is compounded by the paucity of studies clearly documenting the differences between abusive and non-abusive injury and the changing interpretation over time. When confronted with concerns of potential sexual abuse, the pediatrician should obtain key elements of the history such as type, frequency and timing of contact and physically assess the child for gross injuries and infection [65]. Definitive assessment and treatment is increasingly handled by referral to pediatricians with specialized experience in testing, interpretation, and documentation of anogenital findings [71].

The issues surrounding sexual abuse are compounded during adolescence [25]. In surveys of high school students, over 25% reported that they have experienced unwanted sexual contact; in clinical populations, the rates are even higher [72]. A recent prospective study demonstrated that child maltreatment is an independent predictor of later adolescent pregnancies, with birth rates highest for sexually abused and neglected females when compared to a matched cohort [73]. Repeated sexual contact and pregnancy places teenagers at increased risk for several health harms. Repeated sexual contact has been associated with younger ages of sexual initiation, higher rates of depression, anxiety, substance abuse and delinquency.

Most adolescent rape and sexual assault is perpetrated by an acquaintance or relative of the adolescent, with younger adolescents having assailants more likely from the extended family. Increased rates of sexual assault are seen in adolescents with disabilities, alcohol use and other family dysfunction [74]. Males are less likely to report sexual assault, less likely to

receive treatment, and more likely to become perpetrators themselves after being victimized than are female adolescents [75].

Clinicians caring for sexual abuse victims should be trained in the procedures required for documentation and collection of evidence and the steps to minimize the child from further victimization [65, 76-78]. They should inquire about psychological traits and behaviors; also, there should be specific inquiry about the types and timing of reported sexual contact [72]. The examination begins with a comprehensive general examination followed by detailed visualization of the genitals, anus and oral cavity.

Procedures such as colposcopy and video-colposcopy offer ways to document and record trauma, to allow the child to be more relaxed and cooperative during examination, and to begin the process of emotional healing [79]. While it is beyond the scope of this chapter to detail all of the findings associated with sexual abuse, recent research suggests that only limited findings have high specificity, such as lacerations and transections of the hymen and bruising or other injury to the anus and genitals. Several findings which were once thought to indicate trauma are now considered non-specific, accidentally acquired, or congenital variations [66]. Follow-up exams can be vital for evaluating certain lesions, determining the course of healing, and treatment efficacy [80].

While all STIs should raise the suspicion of possible sexual contact, infections with *Neisseria gonorrhea* and *Treponema pallidum* are most specific for mucosal sexual contact and must generally be reported [65, 69]. The presence of STIs needs to be evaluated on a case-by-case basis, and the possibility of non-sexual or vertical transmission considered. Other infections to be considered include *chlamydia trachomatis*, *Trichomonas* species, human immunodeficiency virus and hepatitis B and C viruses. The clinician should be knowledgeable about the potential sources of infection, body sites, types of contact and testing strategies before treatment eradicates microbiologic evidence. There are several new methods being used to detect STIs, not all of which have acceptance in legal proceedings [81-84]. The clinician needs to carefully consider the types and timing of any prophylaxis for STI or pregnancy based on the age and development of the child, the type and timing of contact, and the risk factors for disease in the alleged perpetrator [69].

Psychological Maltreatment

Psychological maltreatment (PM) is commonly associated with other forms of abuse but may also occur in isolation in a small number of cases. By definition, PM is a repeated pattern of interaction between a parent and child that harms the child's emotional well-being. Spurning, belittling, degrading, ridiculing, or shaming a child is considered harming a child's self-worth. Terrorizing and otherwise exploiting the child increases the harm further. The sheer denial of emotional closeness leads to physical and developmental delays in young children and failure to thrive in infants. Rejection, isolation, and inconsistent parenting styles lead children to feel insecure in their home and relationships. An emerging form of PM occurs when a child witnesses violence in the home, including spousal violence, community violence, or even violence on television or movies [84]. PM is seldom the focus of CPS investigation and has increasingly been coupled with other forms of CM in CPS reports [85, 86].

PM is associated with a variety of negative and lasting effects. Shaffer et al. suggested that the effects of emotional maltreatment are disabling and enduring, with adjustment outcomes varying according to the type of psychological maltreatment (i.e., emotional abuse, emotional neglect), gender, and other factors [87]. PM is strongly linked to depression and problems with relationships and attachment, and it predicts more rapid onset of major and minor mental illness in a dose-dependent manner [88-92]. PM and recurrent PM in childhood and adolescence represent important risk factors for increased victimization, and children with high levels of co-occurring internalizing and externalizing symptoms are particularly likely to experience increased exposure to peer victimization, maltreatment, and sexual victimization, thereby escalating physical and mental harm [93].

Psychological neglect and failure to thrive have been significantly associated with behavior problems and poor cognitive development, even while controlling for poverty [94, 95] and services put in place [96, 97]. The psychological effects of maltreatment may be very difficult to recognize in the medical office. Sometimes the poor parent-child relationship is seen and the verbal stigmata of PM exposed, but often there are little or no physical findings demonstrating the emotional harm, other than weight loss or excessive weight gain. The quiet, depressed child is not often identified as a victim of neglect as readily as is the hyperactive, aggressive child [98]. The pediatrician needs to evaluate the harm or potential harm to the child's mental health, while realizing that it may take several years for such harm to become apparent and the effects are often confounded with exposure to other violence [85].

Documentation must be objective, with appropriate use of psychological tests and mental health referrals in the evaluation. Behavioral changes in the child are early but non-specific events, and assessment should include multiple domains, including function at home, school and at play. The psychological effects of malnutrition are further modified by the intensity, type, frequency, and severity of exposure as well as the developmental stage and resiliency of the child [84, 96]. A recent study noted that fewer than 25% of families received counseling, mental health or other services after PM, and service referrals varied significantly based on family race, ethnicity, poverty and co-occurring child maltreatment. When offered, counseling was associated with a 54% reduction in PM recurrence, and other services were not associated with significant reductions [99].

Neglect

Child neglect is the most common form of child maltreatment, affecting 50% or more of children reported annually to Child Protective Services [12]. Dr. Ray Helfer reminded pediatricians about the significant harms caused by the 'litany of smoldering neglect' and the de-emphasis of neglect that has caused mandated reporters to have second thoughts about reporting neglect because little, if anything, could supposedly be done by overwhelmed, understaffed child protective services agencies [100]. Neglect is the omission or lack of a minimal level of care by the parents or caretakers that results in actual or potential harm to the child. Neglect is often associated with poverty, but poor families are not necessarily neglectful [13].

Many subtypes of neglect often occur concurrently, but our understanding of its outcome is often aided by identifying subtypes that can direct potential interventions. Physical neglect

is the lack of food, clothing or shelter; emotional neglect is a form of psychological maltreatment, and educational neglect refers to the lack of proper educational resources. Pediatricians are most likely to identify and treat medical care neglect and failure to thrive resulting in illness [101-103].

The morbidity and mortality associated with neglect are substantial. Although poorly identified on death certificates, child death review teams consistently identify supervisory and other forms of neglect as causing as many or more deaths as physical abuse [104]. Physical conditions caused by neglect include injuries, ingestions, inadequately treated illnesses, dental problems, malnutrition, and neurological and developmental deficits. Manifestations in neglectful families include noncompliance or non-adherence to medical recommendations, delay or failure in seeking appropriate health care, hunger, failure to thrive and unmanaged morbid obesity, poor hygiene and physical and medical conditions contributing to poor cognitive and educational achievement [101].

Poor supervision is less defined but has been broken down into broad categories, consisting of not watching the child closely enough, inadequate substitute child care, failure to protect from third parties, knowingly allowing the child to participate in harmful activities, and driving recklessly or while intoxicated [105]. A comprehensive response requires that the pediatrician address the actual or potential harms that have occurred to the child and to make appropriate referrals to a myriad of community services to address a variety of social and economic issues in the family, including reporting [102, 106].

Management of neglect first centers on properly identifying the sources contributing to neglect. For example, while malnutrition is medically addressed through proper provision of fluids, calories, and protein as dictated by commonly accepted parameters, the pediatrician must also assess the lack of appropriate food, the provision of that food to the child, and the explanation, if any, as to why it was not provided. Important screening questions that can elicit further avenues of intervention include inquiring about the family's access to food, their access to appropriate medical and dental services and medicines, substance abuse during and after pregnancy, homelessness, housing and environmental safety, depression, domestic violence, and degree of supervision [101].

Failure to thrive, otherwise coded as the lack of normal physiological development, is associated with malnutrition in infancy, and has historically been grouped into organic, non-organic (NOFTT), and mixed varieties. NOFTT is more realistically called malnutrition due to neglect. To the extent that many cases fall into the mixed category, it is important to sort out the contribution of neglect in a particular case [96, 103]. While a full discussion of the evaluation of NOFTT is beyond the scope of this chapter, it is important to emphasize that the findings on a comprehensive history and physical examination should guide management and initial laboratory testing. In the face of normal basic metabolic measurements, a careful observation of parental feeding practices and the child's intake and output is often illuminating. Height and weight need to be precisely measured over multiple visits and compared to currently accepted norms, some of which are modified by race, prematurity or other medical conditions. With acceptable weight gain under direct observation and lack of significant medical cause for malnutrition, a presumptive diagnosis of NOFTT can be made and community resources activated.

Challenges for research on child neglect remain, including the changing demographics of the nation and health disparities. Evidenced-based early interventions and treatments may be an opportunity for prevention of child neglect and improving child welfare services,

particularly in an era of health care reform. Developmental researchers across the translational pipeline are encouraged to integrate child neglect research into future studies to inform prevention, treatment and policy efforts for the improved health and well-being of children, families and communities [101].

Special Issues for Adolescents

Pediatricians should be knowledgeable about legal definitions and reporting requirements; they also should provide preventive counseling and screen adolescents for a history of assault and potential emotional effects. They should be knowledgeable about the physical findings associated with sexual assault and testing for STIs and pregnancy and be able to provide these services or refer the adolescent to other providers in the community. There has been considerable growth in treatments available for victims of child abuse and neglect, but adolescents face the additional burdens of developing risk-taking behaviors, paraphilias, and becoming perpetrators as the result of their victimization if not appropriately treated [72, 75]. Sexual abuse, in particular, appears to be a strong risk factor for subsequent perpetration, influencing adolescents and young adults to develop an orientation that is abusive to other children [107]. An adolescent's exposure to a pervasive atmosphere of violence in the home is a key risk factor of future perpetration and suggests the need to address the specific behaviors and risks in the child as well as the overall environment.

There is a proper focus on the need to confront offending behavior while taking into account the developing cognitive and social abilities of the adolescent. Sex offenders report more histories of maltreatment, both physical and sexual, compared to conduct-disordered young people in general. Thus, any treatments must take into account the adolescent's victimization as well as their developing patterns of perpetration and their environment. When young people are identified as being responsible for committing abusive acts against others, it is essential to assess and intervene in their own victimization experiences to prevent post-traumatic stress and other emotional effects. Pediatricians need to be sensitive to the psychological needs of the adolescent and provide initial psychological support after sexual assault while making referrals to appropriate mental health professionals and community resources for longer-term assessment and counseling [74].

Diagnosis

At a minimum, the clinician caring for children should be able to recognize and report potential child maltreatment, using standard methods for obtaining history, physical examination and selected laboratory and imaging tests. This clinician must also be cognizant that multiple forms of maltreatment may co-exist, understand the importance of certain risk factors, assist in choosing the appropriate location and timing of evaluation, and appropriately refer children and families to specialized medical and social services. In health care, a clinical assessment of child victimization begins with a medical encounter that usually follows information-gathering, physical assessment, testing, and clinical diagnosis followed by treatment and referral (see Table 3).

Medical diagnosis of child abuse and neglect follows commonly-accepted practices for other medical diagnosis. Pediatricians should consult current Clinical Procedural Terminology for coding for encounters and International Classification of Disease codes for diagnosis (see Table 2). While the use of such coding does not guarantee reimbursement, it highlights the standard approach to maltreatment as a concern of the health care system and allows collection of population data from hospital discharge and emergency department databases [4].

Medical history, a cornerstone of medical diagnosis, plays the most important part in the diagnosis of child abuse and neglect. It is the history, taken with the physical examination findings and imaging studies, that offers a sound basis for diagnosis and treatment recommendations for the child and family. Inquiring and recording the specific complaints and disclosures of maltreatment by the child and parent, if any, in their own words is vitally important to the ultimate protection of the child. Behavioral and emotional issues are important in this assessment. Certain non-specific behaviors, developmental delays, and history of abuse should be recorded as part of the medical history; this history aids in assessing harm and planning for appropriate treatment [66]. A simple set of screening questions for use during the general pediatric encounter has been developed but has yet to be widely implemented [108]. In cases of child victimization, the content and methods used to obtain the patient's history and the techniques used for physical examination are further specialized to concentrate on areas of increased risk and the types of suspected maltreatment [109].

The practitioner then arrives at an assessment or diagnosis, usually utilizing schema of diagnostic categories, such as the International Classification of Disease [4] or a specialized diagnostic scheme for certain types of abuse [66]. Unique to child maltreatment diagnosis is a determination of certainty. A low level of certainty is required to meet general standards of a 'reasonable cause to suspect' that maltreatment has occurred for mandated reporting.

This presumptive diagnosis leads the practitioner to request diagnostic tests for the child, such as x-rays, blood work, or microbiologic cultures, if such tests are indicated. The presumptive diagnosis also leads the practitioner at the time of the encounter to begin treatment of any acute injury, ensure protection of the child from further harm, and arrange referrals to appropriate physical or mental health specialists for further evaluation and treatment [110].

Treatment, Reporting, and Court Appearance

Pediatricians have historically had an important role in the assessment and reporting of suspected child abuse and neglect, and now have an increasingly important role with mental health professionals, community, and government services in treatment and prevention activities [111]. Medical professionals have had a long history of evaluating children and participating as team members in the interdisciplinary assessment of child maltreatment [112]. Abraham Jacobi, a forefather of modern pediatric medicine, joined the New York Society for the Prevention of Cruelty to Children in New York City in 1881 [113], and multidisciplinary hospital committees were created to address this multidimensional problem

[114]. These “child protection teams” consist of social workers, physicians, nurses, and other child advocates.

A key element is the pediatrician’s understanding of child development, how injuries occur accidentally and non-accidentally, basic concepts of good parenting, and other family violence, such as intimate partner violence and elder abuse. In a recent survey, two-thirds of pediatricians reported treating injuries from child abuse, two-thirds had treated injuries from other community violence, and one-half had treated injuries related to domestic violence [115]. Pediatricians assist the community response by collaborating with community agencies (such as child advocacy centers and social services agencies) and governmental entities (such as police and child protective services) that have the resources, responsibility, and authority to protect and improve the lives of child victims.

Nurses have been increasingly called upon to perform more than routine nursing services in the evaluation of suspected abuse. For example, “Sexual Assault Nurse Examiners” or “SANE” nurses have provided medical examinations for the collection of forensic evidence of suspected sexual and physical assault [116]. In addition, some nurses also visit homes of new parents to help reduce the risk of child maltreatment [117, 118].

Physicians have legal responsibilities to report their concerns of child abuse and neglect to appropriate state agencies in all fifty states in the US [12, 119]. Although the forms of the legislation vary from state to state, these “child protection laws” stipulate that certain professionals must report their concerns of child abuse and neglect to appropriate governmental agencies. The reporting requirements of these laws supersede the confidentiality of medical records and the patient-provider relationship. The “mandated reporters” generally include physicians, nurses, and other professionals working in hospitals, in addition to a variety of other licensed professionals who include teachers, counselors, law enforcement officers, and mental health professionals.

Specific protections are usually given for reports made “in good faith,” and certain penalties are listed for the failure to report when child maltreatment would “reasonably” have been suspected. It is important to note that child abuse reporting is one of the few instances in which health care professionals are required to contact a governmental agency in the routine course of their practice. While disease reporting has traditionally existed within public health (particularly when a contagious infection may pose a hazard to the community’s health), reporting actions that are deemed to be “crimes” have historically been less accepted by the medical community. Less clear statutory requirements have been enacted in the United States for the reporting of victimization of elderly, vulnerable adults, and domestic violence.

Physicians have historically underreported suspected maltreatment [120, 121]. Several reasons have been identified for this failure, such as fear of losing patients, distaste for the legal system and liability concerns [115, 122]. Penalties for not reporting range from fines in some states to criminal charges in others, but also include civil penalties so that the child and/or the child’s family may litigate to redress financial losses sustained because maltreatment was not reported. Recent federal legislation in the United States specifically allows child abuse reporting and exempts such state reporting laws from HIPAA requirements.

Reporting child victimization to governmental agencies begins an investigation to identify the presence or absence of “evidence” to support or “substantiate” the suspicions. Requirements vary from state to state, and no national criteria exist for determining whether to report suspected abuse or neglect. General guidelines have been suggested that include the

patient meeting the definition of being a child, the act or omission having been committed by the parent or caretaker, the acts or omissions lead to harm or the risk of harm, or the features of an episode fulfill other criteria for abuse or neglect in the medical record [123].

Multiple missed medical appointments, unreasonable delay in seeking medical treatment, abandonment, illnesses that could be prevented by routine medical care and inadequate care have been identified as potential minimal criteria for a neglect report [106]. Fractures, soft tissue injuries of normally protected body parts, inflicted traumatic brain injury and witnessed physical injury caused by the caretaker indicate cause to suspect physical abuse. Statements made by the child or parent disclosing potential sexual contact with a caretaker or contrary to state law, certain anogenital injuries, and sexually-transmitted infection are generally a basis for diagnosing suspected sexual abuse.

The ultimate and perhaps most important action to protect a child from further victimization may involve going to court. Physicians and other health care providers are routinely called to provide information regarding their medical evaluation of children, particularly with regard to statements made by the child, the medical history obtained, and any findings of physical examination. While giving testimony in court, physicians and other health care professionals are often asked their opinion, “within a reasonable degree of medical certainty,” concerning the diagnosis of child abuse and neglect or victimization. Significant differences exist between standards for medical diagnosis and those for civil or criminal adjudication. Medical diagnosis is defined as “the act of distinguishing one disease from another” or “the determination of the nature of a case of disease” [124].

A constellation of the patient's history, physical examination, and laboratory findings may result in multiple diagnoses, which may lead the practitioner to a treatment plan without 100 percent or even probable certainty after diagnosis. These criteria differ significantly from legal standards, by which a level of certainty must be carefully crafted to include “credible” evidence, a “preponderance” of evidence, “clear and convincing” evidence, or evidence “beyond a reasonable doubt.” Differences in interpretation of certainty lead to difficulty in communication between legal and medical practitioners.

Court appearance and testimony, while often inconvenient, is vital to provide the evidence and opinion for the state to take action to protect children. Recently, testimony provided by physicians has been considered part of medical practice, and providing “irresponsible testimony” may have negative repercussions for a physician's practice [125]. Despite the legal system's need for health care professionals to provide evidence in maltreatment cases, it is relatively uncommon for health care professionals to be required to attend court hearings, even if they specialize in caring for maltreated children [126].

Training and Prevention

Health care professionals have a unique role in the training of child welfare professionals, law enforcement, child protection services workers, and all professionals who manage the day-to-day care of children. To fulfill their mandatory roles in reporting child abuse and neglect, teachers, child development specialists, mental health workers and others who provide daycare, education, and counseling services need to understand the medical manifestations of child victimization. They also need to identify the physical as well as

emotional signs of abuse and neglect so that they can provide the optimal treatment for children in their care. Professionals from a variety of health care disciplines provide specialized training at a national level for medical and nonmedical providers through multidisciplinary organizations such as the American Professional Society on the Abuse of Children (www.APSAC.org) or medical organizations such as the American Academy of Pediatrics (www.AAP.org). Additionally, various child protective service agencies and university programs render services to nonmedical providers and offer information about medical issues related to child victimization.

The prevention of child abuse and neglect ultimately rests with the family, but pediatricians and the community can still play important roles preventing abuse from occurring [127]. The economic burden, estimated at over \$80 billion annually, calls for prevention [128]. Local county councils for the prevention of child abuse and neglect sponsor programs, social service agencies provide childcare or foster care, and state departments of social services have the legal authority to investigate suspected child maltreatment. Community approaches, such as home visitation, parenting classes, certain cognitive behavioral therapies for children, and parent-child interaction therapy, have been shown to be effective in changing parents' behavior, and reducing social isolation and stress, particularly in families at risk for maltreatment [129, 130].

Preventing child abuse and neglect spares children physical and psychological pain and improves their long-term health. Dubowitz [131] noted that prevention "is intuitively and morally preferable to intervening after the fact." There is increasing evidence supporting the effectiveness of several universal and selective prevention interventions the effectiveness of most programs is still not known [132, 133]. Robert Caldwell [134] estimated that the costs of a home visitor program in Michigan would be 3.5% of the \$823 million estimated cost of child abuse, and small reductions in the rate of child maltreatment were thought to make prevention cost effective. However, home-visiting programs are not uniformly effective, parenting programs appear to improve parenting but not necessarily reduce child maltreatment, and some family programs are successful in reducing physical abuse but not neglect.

Ray Helfer [135] noted the "window of opportunity" that is present in the perinatal period to enhance parent-child interactions and prevent physical abuse. Several program models have shown promise based upon key periods, including pre-pregnancy planning, early conception, late pregnancy, pre-labor and labor, immediately following delivery, and at home with the child. Opportunities for prevention include teaching parents and caregivers to cope with infant crying and how to provide a safe sleep environment for their infant. A meta-analysis of several early childhood interventions concluded that the evidence for their preventing child maltreatment is weak, but longer-term studies may show reductions in child maltreatment similar to other programs such as home visiting, when longer follow-up can be achieved [136].

Several parent education programs have been evaluated for their association with decreases in physical abuse and neglect. Family Connections, a multifaceted, home visiting community-based child neglect prevention program, showed "cost effective" improvements in risk and protective factors and behavioral outcomes [137]. To address a specific form of physical abuse, Mark Dias and colleagues devised a hospital-based parent education program implemented immediately after birth that has been shown to decrease the incidence of shaken baby syndrome [138, 139]. Barr and colleagues [140] have devised a program of parent

education in late pregnancy, delivery, and early infancy to change maternal knowledge and behaviors relevant to infant shaking. Using a randomized controlled trial, they were able to demonstrate how “The Period of Purple Crying” was able to increase maternal knowledge scores, knowledge about the dangers of shaking, and sharing that information with other caretakers.

A randomized trial of the “SEEK” program in an inner-city clinic with high-risk families was able to show lower rates of maltreatment, CPS reports, harsh punishment, and improved health services after an intervention of pediatric resident education [141]. Several barriers (time, training, culture, sensitive issues) to widespread implementation could be addressed by identifying potential strategies, such as the use of handouts and local news stories, to begin a dialogue during routine pediatric visits [142].

With the generosity of the Doris Duke Charitable Foundation, the American Academy of Pediatrics launched a program called Practicing Safety: Connected Kids aimed at decreasing child abuse and neglect by enhancing anticipatory guidance and increasing screening provided by pediatric practices to children ages 0-3y, focusing on helping parents and families to raise resilient children [143]. Anticipatory guidance has significant potential for decreasing violence, and each counseling topic discusses the child’s development, the parent’s feelings and reactions in response to the child’s development and behavior, and specific practical suggestions on how to encourage healthy social, emotional, and physical growth in an environment of support and open communication. Practices screened for maternal depression and improved their discussion of coping with crying, maternal bonding, toilet training and discipline [143].

Sexual assault and rape prevention strategies begin with the child and family being able to identify and avoid high-risk situations and immediately reporting potential sexual contact. Pediatricians and others can provide screening for victims of domestic violence during routine medical care and can provide guidance and strategies to prevent or minimize abuse (such as avoiding late night use of alcohol or drugs or seeking immediate medical care after assault). Finkelhor (2007) has concluded that the available evidence supports providing high quality child-focused prevention education programs because children are able to acquire the concepts, the programs promote disclosure, there are lower rates of victimization, and children have less self-blame. Parent education and media campaigns have also demonstrated some positive effects [144].

A review confirmed the effectiveness of school-based sexual abuse prevention [145]. Pediatricians have the ability to explain child development and the special health needs of children, particularly those with chronic medical conditions, to the community and to provide the scientific background and structure for the implementation and evaluation of community programs. Prenatal clinics and other services for high-risk adolescents need to provide primary care interventions to prevent future maltreatment.

CONCLUSION

Pediatricians and other clinicians play a vital role in the assessment, identification, care, and treatment of victims of child abuse and neglect. Physicians, nurses, and other health professionals have developed increasingly sophisticated techniques for diagnosing and

documenting physical abuse, head trauma, fractures, anogenital trauma, and sexually transmitted infections. They have integrated such diagnostic findings with referral to specialized services. They are important members of the crew of the 'lifeboat' needed to save children in the sometimes turbulent 'ocean of life' [146].

While C. Henry Kempe first taught us about the battered child in 1962 and Ray E. Helfer showed the importance of understanding a child's perspective in 1984, we still have a long way to go in solving the problems of child neglect and victimization in our communities. Many segments of our population do not understand the impact of higher rates of poverty, unique health concerns, and other special circumstances of children. Our response to the needs of abused and neglected children requires earnest dedication by all medical professionals in clinical care, training, research, and advocacy to identify, treat, and prevent the devastating physical and emotional consequences of child abuse and maltreatment.

Chapter 513

PUBLIC HEALTH ASPECTS OF YOUTH SEXUAL OFFENDERS

Helen D. Pratt,* PhD

and Donald E. Greydanus, MD, DrHC (Athens)

Department of Pediatric and Adolescent Medicine, Western Michigan University,
Kalamazoo, Michigan, USA
Homer Stryker MD School of Medicine,
Kalamazoo, Michigan, USA

ABSTRACT

Children and adolescents under the age of 18 years account for one-fifth of arrests for all sexual offenses (excluding prostitution). These young perpetrators can be found among all socio-economic groups and live in all regions of the United States. They often come to the attention of primary care clinicians when their parents bring them to the office for protection from the authorities and help with addressing their maladaptive behavior. Clinician-collected information may get used as a part of criminal investigations or to facilitate initial evaluation and coordination of services. Frequently, parents will bring their child or adolescent in for an office visit once the parents have caught them engaging in some form of sexual activity. The parent's concern is typically whether or not this is normal or abnormal behavior. Physicians who are aware of adolescent sexual offending can increase their ability to detect adolescents who have aberrant or deviant sexual behavior patterns allowing for *early* referral and comprehensive intervention.

Keywords: childhood, adolescence, behavior, crime, sexual offense, sexual offenders

INTRODUCTION

Most of the sexual abuse literature focuses on adult perpetrators or child/teen victims. In the past five years, only a few new articles have been published discussing adolescent sexual offenders [1-4]. Most of those articles consisted of meta-analyses of previous studies. The office of Juvenile Justice Delinquency and Prevention, National Center on Sexual Behavior of Youth (NCSBY) has published statistics (2009-2011) on youth sexual offenders [1-4]. Otherwise there has not more current data since the original article by the authors of this chapter who have published on adolescent sexual offending [5-7]. There is still a paucity of data available in the literature on adolescent sexual offenders who are involved in sexual abuse of younger children. Primary care clinicians must be prepared to act in a manner that does not contaminate forensic evidence nor alter the testimony of either the perpetrator or victims in a legal trial. Clinicians may encounter these youth in their practices under several circumstances: adolescent revelation, parental report, or at the request of legal representatives.

What we know about sexual offenders, in general, is based only on those individuals who are caught or prosecuted. Even youth who are caught, arrested, and convicted frequently receive minimal punishments (i.e., probation, community service). The costs to society for the crimes of juvenile sex offenders are considerable, not only for those inflicted on crime victims and society as a whole, but also for those imposed on offenders and their families. The rehabilitation focus of interventions for those youth referred to treatment programs is considered to be controversial because the interventions are not evidenced-based for the adolescent sexual offender population. Most adjudicated adolescents live and are treated in community settings and often reoffend. Unfortunately, there remains little empirical evidence of the long-term effects of different interventions with adolescent sexual offenders [5-7].

DEFINITION

Adolescent sex offenders are defined as youth between the ages of 13 and 17 years who commit illegal sexual behavior as defined by the sex crimes statutes of the legal jurisdictions in which they reside. Legal meanings of sexual offenses vary from state to state [10]. However, statutes typically define sexual offenses in terms of: a) penetration offenses, which include penetration of virtually any body orifice for a sexual purpose, and are felonies; and b) crimes not involving physical contact (e.g., voyeurism, exhibitionism, obscene phone calls). Such offenses progress from privacy issues at the misdemeanor level to the felony level, depending on the specific circumstances of each case. The addition of physical force or coercion will almost always result in a felony life offense. Most adolescents are not sexual predators, nor do they meet the accepted criteria for pedophilia [9].

EPIDEMIOLOGY

The incidence of sexual victimization of children by adolescents has become a serious problem in our society. Juveniles account for more than one-third (35.6 percent) of those

known; less than 1 percent of all arrests of youth 17 years of age and younger were for sex offenses [3]. Each year, there are approximately 2,200 arrests of juveniles for forcible rape and this includes an additional estimated 9,200 arrests of juveniles for other types of sex offenses. The percentages of adolescents arrested for sexual offending in 2010 were for youth in the following age groups: younger than 9 years (5%); younger than 12 years (16%); between ages 12 and 14 (~13%), and between ages 15 and 17 (46%) [10-12]. The vast majority (93 percent) were male. The number of arrests of juveniles in 2010 was 21% fewer than the number of arrests in 2001.

CLINICAL FEATURES

Adolescents do not typically commit sex offenses against adults, although the risk of offending against adults increases slightly after an adolescent reaches age 16. Sexual offenses against other children are more likely to offend in groups, at school, have more male victims, and have younger victims. Sexual offenses against young children are typically committed by boys between the ages of 12 to 15 years of age. In 2011, 53% youth arrested for sexual offences involved youth younger than 16 and 28% involved females [14-16]. Most females adolescents sex offenders were mainly younger than their male peers, had more multiple-victim and multiple-perpetrator episodes, and their victims were primarily family members or males.

Researchers generally agree that there are *multiple* factors (psychological, biological and sociological) that interact in complex and poorly understood ways; these factors include the adolescent's temperament, cognitive abilities, impulse control, family variables, and socioeconomic factors as well as access to potential victims and opportunities to offend. A number of factors have been found to be associated with a higher prevalence of adolescent sexual offending and these include a history of prior physical or sexual abuse, impaired family functioning, alcohol and substance abuse, exposure to erotica, neurobiological factors, and psychiatric co-morbidity.

However, we do not know specific and direct causation. Adolescent sex offenders are considered to be more responsive to treatment than adult sex offenders and do not appear to continue re-offending into adulthood, especially when provided with appropriate treatment. Across a number of treatment research studies, the overall sexual recidivism rate for adolescent sex offenders who receive treatment is low in most US settings as compared to adults. Adolescents who offend against young children tend to have slightly lower sexual recidivism rates than adolescents who sexually offend against other adolescents. Adolescent sex offenders' rates for sexual re-offenses (5-14%) are substantially less than their rates of recidivism for other delinquent behavior (8-58%) [12].

Presentation in the Office

The serious psychosocial and legal implications for the offender and his or her family often prevent parents from seeking help. More often the offender will be brought to the physician by an appropriate agency in the course of a child abuse investigation for

a) assistance with medical and psychological evaluation, b) to facilitate further expert evaluation, c) specialized referral, or d) to co-ordinate on-going care.

Sometimes parents may bring their teen in with concerns about his or her social development and provide indirect or non-specific indicators of an adolescent being involved in the sexual abuse of younger children. The parent may express concern about their teen's sexual activities with a younger child (i.e., sibling, other relative, or acquaintance); they may also ask if such activities are "normal." Also, the parents of victims may report fear of the offender or incidences of sex play between their young child with an older teen to the offender's parents; then the offender's parents presents that information to the physician. The goal of the parent is for the physician to tell them how to help their offending adolescent.

Most offenses are committed by a small number of adolescents who repeatedly reoffend and account for the molestation and sexual abuse of half of the male victims and one quarter of the female victims. Juveniles who have committed sex offenses are males who represent a heterogeneous mix, commit multiple offenses, usually have more than one victim, and usually offend against females; if they violate very young children, then their victims are usually male. Unfortunately, they may have several types of victims. The juvenile offenders differ according to victim and offense characteristics and a wide range of other variables, including types of offending behaviors, histories of child maltreatment, sexual knowledge and experiences, academic and cognitive functioning, and mental health issues. They usually have not been victims of childhood sexual abuse. Also, very little data are available on female sexual offenders [10-16].

Adolescent sex offenders rarely have previous convictions for sexual assault, but are likely to have committed nonsexual offenses. Those who have been physically abused were 7.6 times more likely to rape or sodomize other children when compared to adolescents who were sexually abused or neglected [5-7]. One in two adult sex offenders began their sexually abusive behavior as a juvenile. Adolescents who commit incest offenses do so in the victim's home and often when providing child care services. Adolescent rapists, on the other hand, tend to victimize strangers. As the age of the victim increases, sexual intercourse becomes a part of the offense.

The families of adolescent sexual offenders tend to be two parent families, have at least one sibling living with them, and more closely resemble those of youth with severe emotional or behavioral problems. Their parents often deny sexual tensions and exhibit a paucity of sexual knowledge or education; also, one quarter of their parents have known sexual pathology. Adolescent sexual offenders who had committed sexual homicides experienced exaggerated personal and family dysfunction [5-7].

DIAGNOSIS

A significant percentage of reported criminal sexual acts against children are various types of paraphilias. The *paraphilias* represent a diagnostic category in the 2013 *Diagnostic and statistical manual of mental disorders, Fifth edition (DSM-V)* and consists of the following subcategories: exhibitionism, fetishism, frotteurism, sexual masochism, sexual sadism, transvestic fetishism, voyeurism, and pedophilia [8]. The victimization is by perpetrators who have intense sexually arousing urges, fantasies, or behaviors; also, a number

of other issues are involved in adult perpetrators, though this discussion involves children and adolescents. The reader is referred to the *DSM-V* for further details in this regard. A psychiatric diagnosis is made if the behaviors have occurred for at least six months and caused distress or impairment that impedes social, occupational, or other important areas of functioning [8]. Pedophilia is the diagnosis of our focus and involves sexual activity with a prepubescent child or children (generally ages 13 years or younger). Perpetrators should be age 18 years or older and be at least 5 years older than their victims.

Sexual Exploitation Versus Normal Sexual Play

When a parent presents with a teen who was accused or caught engaging in sexual play with a younger child or a developmentally younger child, the physician may be asked to tell the parent if this is normal or not. The physician who understands the differences between sexual *exploration* and *exploitation* will be better prepared to make that distinction when faced with a report of adolescent sexual behavior. “Normal” or *developmentally sexual curiosity* and exploration are a normal part of the developmental play and should meet the criteria listed [5-7, 16]:

- 1) The two involved individuals who are age and developmental peers.
- 2) Children and pre-pubertal adolescents may engage in exploratory behaviors.
 - The play or exploration usually involves only mutual genital display, touching, and fondling.
 - Curiosity about the differences and similarities in anatomy is normal.
 - Exploratory sexual play is not coercive.
 - Mutual consent is typical of exploratory behaviors.
 - Does not include multiple participants.
 - Observers or additional participants are not acceptable.
 - Manifestations of anger, fear, sadness, or other strongly negative responses are not present.

Exploitation involves the absence of the factors listed above and the inclusion of the following:

- If one of the individuals is cognitively impaired, then a peer relationship does not exist.
- Attempted intercourse is atypical among preschoolers and is rare in the young school-aged child (6-9 years).
- Abusive behavior often involves elements of pressure, misrepresentation, force, threat, secrecy, or other forms of coercion. Although some of the threat or coercion is obvious and violent, the evaluator must take care to recognize subtle emotional pressure or the use of implied authority by an older child or adolescent in some cases.
- If the sexual contact has been arranged for the pleasure of another older individual, it is exploitative. One of the participants manifests feelings anger, fear, sadness, or other strongly negative responses.

- The victim views the experience in negative terms; however, some abused children will appear to have a neutral or positive emotional response to this abuse.

Regardless of whether or not the sexual play is normal or abnormal, parents and adult caregivers need to be vigilant and give children other healthy outlets. Parents should be encouraged to always keep young children under surveillance, especially when older individuals are around.

If the “sex play” is determined to be experimental or exploratory, the physician should discuss normal childhood and adolescent sexual behavior with parents and outline measures to minimize inappropriate sexual stimulation in the home. Parents should be advised to provide closer supervision of the adolescent. Older adolescents can be instructed to stay away from compromising situations with younger children [16].

Co-Morbid Disorders

Adolescent sexual offender can have concurrent diagnoses of psychopathology. They rarely exhibit behavior problems; they are more likely to be shy, and more comfortable with younger children. The most common psychiatric diagnoses, respectively, are conduct disorder, substance abuse disorders, adjustment disorders, attention-deficit/hyperactivity disorder, specific phobia, and mood disorder. They frequently engage in distorted thinking to make their offenses more socially acceptable to themselves and others; much like other delinquents, their distorted thinking allows them to excuse their offenses. Male offenders are more often diagnosed with paraphilias and antisocial behavior. Female offenders are more likely to be diagnosed with mood disorders and engage in self-mutilation [8, 11, 13, 14].

INTERVENTION

In most states adolescent sexual offenders can be adjudicated for criminal behavior as young as 6 years old. However, most states set 10 years as the lowest age of criminal responsibility. Victim consent is not always considered important. Once there is sufficient evidence to identify an offender, a decision regarding prosecution is often made at the juvenile court level. If the child or adolescent goes to trial, the setting in the juvenile justice system is usually less formal and hearings are often conducted in private without the use of a jury. Juveniles in this system are more likely to receive efforts at rehabilitation and less likely to be held fully accountable for their actions, than if they were adjudicated in the adult courts. However, in the case of rape, sodomy or sexual homicide, most states have moved to address adolescent offending in the adult criminal justice system, which can impose harsher punishments.

Local statutes usually govern physician-patient privileges (i.e., the right to respect the confidentiality of all communications). Thus, the development of such privileges in each state is subject to *local* interpretation and state-by-state case law developments. Physicians should explain, at the outset, to all adolescents and their families the limits of confidentiality. If the

adolescent's behavior must be reported to the authorities or potential victims warned, the physician should inform the patient and the family.

Professionals, who deal with children, have an *enforceable* mandate to report *suspected* child abuse. All fifty states have "mandated reporting" laws which require professionals to report "reasonable suspicions" that abuse or neglect has occurred. Professional obligations pertaining to confidentiality may be seriously challenged by the requirements of the law and the local community, particularly when it involves sexual conduct. It is helpful to explain to the parents and the patient that reporting any crime changes the status of the act from private to criminal; however, this is required as part of mandatory reporting laws.

No clinician should consider serving as a witness or expert witness in sexual abuse cases involving adolescent offenders without *specific* training in this area. A more definitive treatment may not be within the purview of all clinicians and generally, the adolescent offender will be referred to professionals and programs specializing in such treatment [3, 14, 18].

RECIDIVISM

The most beneficial treatment program identified in the treatment literature is multi-systemic therapy (MST) [19]. Outcome studies contend that MST has its best effects on youth who engage in antisocial and deviant sexual behaviors. This treatment showed that interventions increased caregiver follow-through on discipline practices as well as decreased caregiver disapproval of their child's behavior. When compared to recidivism rates between adults and juvenile sex offenders, the juvenile sex offenders appeared to have lower recidivism rates and perform better in treatment than (5-14%). Those adolescents who offend against young children tend to have slightly lower sexual recidivism rates than adolescents who sexually offend against other teens. Adolescent sex offenders' rates for sexual re-offenses are substantially less than their rates of recidivism for other delinquent behavior (8-58%). Research has shown that a young person who commits a sex offense is unlikely to commit another one [1-4, 11, 14].

In the event that the physician determines that sexual abuse has occurred, he or she should follow the guidelines from the governing child protective services organizations and medical oversight organizations; also, medical examination and documentation should be performed as required by state child abuse laws. The family should be referred to the appropriate agency for further evaluation. If the adolescent has access to other children, especially very young ones, the physician should assess the level of risk posed to those children.

When it is determined that the child or adolescent is at high risk of sexually offending, then the physician should inform the family and the appropriate persons. Furthermore, the family should be advised to:

- **STOP** all baby-sitting and childcare activities under all circumstances!
- Parents must provide enhanced/additional supervision of their offender.

- The youth offender should not have access to young children or potential victims without direct supervision by a responsible adult who is aware of the problem---especially in school, churches or other related activities.
- The child or adolescent offender should not have access to, possession of or use of sexually explicit, "x-rated," media or pornographic materials.

The physician can encourage parents/care-providers to allow their youth sexual offenders to engage in most ordinary daily activities, such as going to school, church, stores, or restaurants with family, or involvement in age-appropriate and appropriately supervised peer activities. However, caution that one of the parents'/care-givers' major responsibilities is to limit the child/adolescent offender's opportunity to re-offend.

CONCLUSION

Children and adolescents under the age of 18 years account for one-fifth of arrests for all sexual offenses (excluding prostitution). They commit multiple offenses, usually have more than one victim, and may not limit their offenses to one type of victim. These young perpetrators can be found among all socio-economic groups and live in all regions of the United States. They often come to the attention of primary care clinicians when their parents bring them to the office for protection from the authorities and help with addressing their maladaptive behavior. Because most offenders are not detected, and those who are discovered are not often adjudicated, the physician can help to prevent and minimize the occurrence of sexual offending by educating parents about the importance of close supervision and seeking appropriate professional help for deviant sexual behavior in children and adolescents.

INTESTINAL/LUNG/LIVER FLUKES: A PUBLIC HEALTH CONCERN

Richard R. Roach*, MD, FACP and Christina Lang, MD

Western Michigan University Homer Stryker M.D. School of Medicine,
Kalamazoo, Michigan and Mustegon, Michigan, USA

ABSTRACT

Current estimates indicate that 50 million people are infected with food-borne trematodes. This is a significant public health problem, but still a neglected tropical disease, because the burden of disease is in rural areas, where health care is limited. Traditional ingestion of raw or poorly cooked food contaminated by unrestrained defecation maintains the cycle of disease, and school-age children bear the predominant burden. Clinical patterns of infection, current means of diagnosis, treatment and treatment failure are reviewed in sections on intestinal flukes, liver flukes and lung flukes. New therapeutic approaches are emphasized.

Keywords: public health, tropics, flukes, food-born trematodes

INTRODUCTION

Of the 50 million people infected, most are in China, Japan, Korea and parts of Southeast Asia including Indonesia, Vietnam, Thailand, Laos and Myanmar [1]. Paramphistomatidae occurs in Africa, Echinostomatidae is endemic in India, and Hereophyidae has been reported in Brazil. International travel has made this a world-wide problem. People contract these infections by eating raw or undercooked fresh-water fish or water plants such as watercress with encysted metacercaria. Infestation of human trematodes is related to their migration.

Intestinal, pulmonary and liver flukes present distinct clinical and diagnostic problems to physicians and health care workers who care for patients with neglected tropical diseases.

SECTION 1: INTESTINAL FLUKES

More than 70 species of intestinal flukes have been reported in humans [1, 2]. The most common are *Fasciolopsis*, *Echinostoma*, *Gymnophallidae* and *Heterophye* species. The cysts of *Fasciolopsis* are ingested when eating aquatic plants such as water hyacinth, water chestnuts, water bamboo and water lotuses, many of which are preferred raw. *Echinostoma* is encysted in fish, mollusks and amphibians which are eaten raw or incompletely cooked. Freshwater fish, carp and mullet, contain *Heterophye* cysts. *Gymnophallidae* contaminate both mollusks and vegetation. The ingested cysts, released in the duodenum, attach to the mucosa and mature into adult worms over a period of 3 months.

Epidemiology

Fasciolopsiasis is endemic to Southeast Asia and the Orient. The disease has the highest prevalence in school-age children [3]. Reported prevalence is 57% in mainland China, 25% in Taiwan, 50% in Bangladesh, 60% in India and 10% in Thailand. Control programs with effective medications have not achieved success due to continued traditions of eating raw aquatic plants and contact with domestic pigs. Change in traditional practices is slow. Although simply drying plant products kills the parasite, this practice is not acceptable in many local customs, and cooking is thought to destroy the flavor.

Recognition of the disease in Africa and reports of the disease in Brazil, Russia, Spain, Turkey and the Philippines have raised awareness of this neglected disease. The economic impact of the disease is difficult to assess but clearly affects rural communities depending on subsistence agriculture.

Clinical

Food-borne trematodes predominantly infect children in endemic areas. Many are asymptomatic but heavy infections produce severe diarrhea, abdominal pain, low-grade fever and fatigue. High inoculums cause malabsorption due to villous edema and atrophy. When cysts attach to the mucosa in duodenum and jejunum they cause inflammation, ulceration and micro-abscesses. Eosinophilia occurs as an immunologic response to trematode protein and toxins and is directly related to worm load [4]. Children tend to become re-infected after treatment, amplifying the clinical problems and confusing the understanding of which treatments are effective, and when and if eradication occurs with treatment. Flukes mature in 3 months and have an average life span of 1 year in humans [2].

Although a few flukes are asymptomatic, heavy worm burdens, considered > 500 worms cause intermittent diarrhea, constipation, anorexia, nausea and vomiting [5]. Diagnosis depends on the detection of *Fasciolopsis* eggs in stool samples. Morbidity in endemic areas is

related to anemia from chronic blood loss, malnutrition due to malabsorption from villous damage and toxic worm metabolites which are thought to cause a variety of symptoms and immunologic reactions that result in facial and generalized edema [6]. Mortality is related to malnutrition, intestinal obstruction and electrolyte abnormalities.

The *Heterophyids* infect humans eating fish or shrimp infected with viable metacercariae. Infected fish-eating mammals and birds contain the egg-producing *heterophyids*. Feces from these creatures contaminate the water and release eggs. Ingested by snails cercariae are released from the snails and then penetrate fish and shrimp in which they encyst. An Egyptian study showed fish to have the greatest intensity of infestation during the summer months [7].

Human prevalence studies in Korea showed the highest prevalence in young and middle aged adults [4]. A national survey to determine the prevalence among primary school children in Laos was unable to differentiate *Opisthorchis viverrini* (a liver fluke) from intestinal flukes [29], so most studies just report stool collection samples as ‘*Opisthorchis*-like’ eggs. Verification of disease burden by purging and stool analysis is therefore complicated by infection with multiple species that cannot be differentiated. A study of cysts in fish dishes in Vietnam restaurants showed a greater prevalence in freshwater than in brackish water fish [8]. Prevalence in Vietnam is as high as 70% depending on the region [7]. *H. tauchi* infection, though rare, is different from other flukes because it enters the mesenteric lymphatics and migrates to the heart causing myocarditis, chronic congestive heart failure, and death.

Gymnophalloides seoi contaminates raw oysters. Infestation tends to be restricted to focal geographic areas. One village in Korea had a 70% infestation rate [9], dramatically higher than the neighboring populations. The usual symptoms are indigestion, constipation and diarrhea. Microscopic examination of gastric mucosa in animal models demonstrates stimulated goblet cell production. In humans, infestation has been associated with diabetes mellitus because it causes acute pancreatitis. One study noted subsequent insulin deficiency in 46% of 37 infected patients. A case study described patients with polyuria and polydipsia but without increased blood glucose or glucosuria [10], but the cause was not elucidated. Infections with *Gymnophalloides seoi* are associated with polyuria and polydipsia and are probably toxin related [11].

Diagnostics

There are three approaches to diagnosing fishborne zoonotic trematodes: detection of parasite eggs in stool, immunodiagnosics (indirect diagnosis) and molecular biologic testing.

Detection of eggs is the most common approach, especially in epidemiological surveys. Methods include fecal flotation in salt and sugar solutions, the Kato-Katz technique and the formalin-ethyl-acetate technique [1]. Trematode species identification based on egg morphology is challenging because *F. buski*, *F. hepatica* and echinostomes all appear similar. *Heterophyids* egg-laying capacity is low, 2-28 eggs per worm (*Ascaris* by contrast produce hundreds of thousands of eggs per day) and the eggs resemble *Clonorchis* spp. A definite diagnosis can be obtained by examination of adult worms after chemotherapy expulsion.

Several tests to detect specific antibodies are available but many have low specificity and cross-reactivity. Enzyme-linked immune-absorbent assays have been developed, but consensus on their use has not been established. Recently, polymerase chain reaction [PCR]

methods have been developed to identify trematode eggs [12]. They will likely prove to be an effective research tools, but use in endemic areas is likely to be impractical in the near future. While metabolic profiling is a new approach to research, its application with intestinal trematodes is presently limited.

Treatment

A single 15mg/kg dose of Praziquantel is generally adequate for children, but adults should receive 25 mg/kg [3]. Various authors have reported that a single dose ranging from 10–40 mg/kg is curative and safe. Praziquantel is not approved for children under the age of four, but its use may be therapeutically necessary. Ivermectin is an alternative choice for children under 4 who weigh greater than 15 kg.

It has been the standard to delay treatment of pregnant women with Praziquantel until after delivery and to avoid breast feeding for 72 hours after administration of Praziquantel. The exception has been if treatment is required for saving the pregnant woman's life. However there are now more than a dozen studies such as Webb et al. in which Praziquantel has been given to pregnant and breast-feeding women [13]. There are no studies that show harm to the mother or fetus, nor are there any animal studies which show fetal harm. In fact, WHO published a bulletin 2002 which reviewed the clinical and veterinarian studies and concluded that the drug was safe despite the manufacturer's cautious recommendations [14].

Prevention

The key to prevention is education and avoidance of raw, water-derived food (for preventing *F. Buski*), raw fish (for preventing intestinal trematodes) and raw oysters from endemic contaminated locations. This has been difficult because of culinary traditions in endemic areas. Other prevention methods include treatment of infected people and livestock and increased sanitation methods to prevent infected humans and pigs from defecating near water sources. Ironically, industrialization has polluted streams and rivers, destroying the environment for aquatic animals and breaking the ecosystem life cycle which reduced the incidence and prevalence of disease in previously endemic areas [15].

Public programs address the role of animal carriers including dogs, cats, pigs and wildlife. In Vietnam, studies of fish-borne trematodes showed prevalence in cats, dogs and pigs of 48.6%, 70.2%, 35-56.9% and 7.7-14.4% respectively [16]. While pigs are generally confined and their prevalence rates are lower, their total fecal contribution is huge which makes pigs significant contributors to endemic regions. Education is important to avoid feeding domestic animals contaminated feed such as raw fish and oysters. However this is impractical for free-roaming animal reservoirs such as cats and dogs. In the commercial fish farms, practices that prevent introduction of infection and quality control are of the utmost importance.

SECTION 2: LIVER FLUKES

Opisthorciasis and clonorchiasis are primarily diseases of Southeast Asia, ranging from China to Indonesia and from Thailand to the Philippines. *Clonorchins sinensis* eggs have been found in a corpse buried in the 4th century BCE [17]. These trematodes, of which 18 varieties are known, penetrate the skin and encyst fresh water fish. Consumption of raw or undercooked fish release the harbored metacercariae to migrate in the human host.

Clinical

Liver flukes migrate through the ampulla of Vater into the common bile duct and from there infest the intrahepatic bile ducts where they cause hepatomegaly, cholangitis and periportal fibrosis. This infestation precipitates gallstones and causes cholecystitis. Ultrasonography often demonstrates gallbladder sludge and poor contractile function. In one study, intrahepatic duct dilation was noted in 68% of egg positive patients with sludge reported in 20.8%. Higher grade dilation was found to correlate with higher egg counts. Periductal fibrosis was also a common finding [18]. Treatment with Praziquantel improves biliary function and decreases intrahepatic duct dilation.

More important than the acute manifestations is the predisposition these parasites cause to bile duct cancer and cholangiocarcinoma. Thailand has the highest incidence of liver cancer in the world. Recent research has noted an exacerbation of hepatic carcinoma by N-nitrosamine. Noteworthy is the fact that N-nitrosamine levels are highest in tobacco, but it is also found in beer, fish and pickles. Tobacco product marketing in Southeast Asia historically correlates with a dramatic increase in hepatic carcinoma. Although this may be due to better case identification, cigarette smoking may be exacerbating the parasitic predisposition to hepatic cancer.

Treatment

A single 40mg/kg oral dose of Praziquantel is effective, but some authors note three divided doses of 25mg/kg as a more effective dose for treating clonorchiasis. This higher dose is associated with dizziness, vomiting and abdominal pain, but these side-effects tend to be transient. Other treatment options have been investigated and tribendimidine seems to be as effective as Praziquantel for *Opisthorchis* [19].

Prevention

If culture continues to mandate eating raw fish, then improved sanitation is the only prevention and control measure available. Molluscicides are not proven effective, are expensive and associated with an increase incidence in community disease when the snails inevitably return. Prevention should be focused on community education, especially school-aged children, for long-term control.

SECTION 3: LUNG FLUKES

Paragonimus species, lung flukes, are contracted from eating raw freshwater crabs and other crustaceans [17]. Although known to be a problem in Southeast Asia recent literature has demonstrated significant prevalence in South America [20, 21] and Africa [22]. There are about 15 species known to infect humans world-wide.

Clinical

Infection occurs when the parasite migrates into the human body and releases toxins and other proteins during migration. Pulmonary infection with cough is often non-productive, but when it is productive, gelatinous, brown sputum from pulmonary hemorrhage is characteristic. Hemorrhage is associated with leukocyte infiltrate and necrosis of the lung parenchyma. The tissue reaction leads to fibrotic encapsulation, but opening in the capsule releases fluke eggs. Hemoptysis with exertion is often reported.

The prominent bronchospasm is often misinterpreted as asthma. Prominent eosinophilia, 20-25%, is common. Persistent pleural effusions, unresponsive to parasitic treatment are related to chronic granuloma reaction. It is not uncommon that lung fluke infestation is diagnosed as tuberculosis, especially in communities where both diseases are endemic. Pneumothorax related to the inflammatory reaction and secondary bacterial infection in the infarcted lung has been reported. The immune response eventually modulates and calcification surrounds the cysts.

Extra-Pulmonary Syndromes

Cerebral migration causes eosinophilic meningitis with headache and seizures. This extra-pulmonary syndrome seems to have a predilection for male children who are under ten years of age. Spinal cord migration causes spastic paraplegia. The neurologic manifestations are usually accompanied by pulmonary symptoms. Neurologic complications such as mass effect and intracranial hemorrhage have required surgical intervention [23].

Diagnosis

The differential diagnosis of lung flukes includes tuberculosis as well as common causes of pneumonia. Clinicians need to be aware of the diagnosis in endemic areas, especially when there is eosinophilia. A careful history of exposure in travelers or patients who have migrated from endemic areas is essential since the parasite can persist for decades. Smear examination of expectorated sputum, gastric washings, pleural fluid, feces reveal eggs in infected individuals, but tissue biopsy is sometimes required. Immunodiagnostic tests are highly sensitive [24]. Complement fixation and enzyme-linked immune-osorbent assay [ELISA] tests are able to diagnose chronic infection and can monitor treatment since they decline with cure.

Treatment

Praziquantel appears to be the treatment of choice, but treatment with bithionol is still reported to be effective [25]. Treatment causes an inflammatory response, so skin lesions can flair, cerebral edema can result from neurologic infestation and pulmonary symptoms may worsen.

Prevention

Discouraging consumption of raw crustaceans is still the best prevention, but dietary custom and culture often mitigate this solution. Local customs of soaking raw crustaceans in brine or alcohol [26] to kill parasites does not appear to be effective. Community awareness and environmental sanitation can be successful. Cobalt-60 irradiation of crustaceans can prevent parasite infectivity but this requires significant economic and public health commitment.

CONCLUSION

Approximately 50 million people around the world are infected with food-borne trematodes which causes an enormous global public health burden. Much of this neglected tropical disease is round in rural parts that typically have limited health care for these infected persons. This discussion reviews epidemiology, clinical features, diagnostic measures, and treatment options for these infections from intestinal, liver, and lung flukes. New diagnostic treatment options have been developed and research will continue to provide improved treatment and renewed hope for those infected [27-30].

ABSTRACT

Leishmaniasis is a serious public health problem endemic in more than 88 countries worldwide. It mainly affects large areas of the tropics, sub tropics, and the Mediterranean basin. More than 350 million people are considered at risk of acquiring the disease and approximately two million new cases occur annually. The disease is caused by Leishmania, a protozoan parasite, and is transmitted by a sandfly vector. Leishmaniasis exists in three clinical forms (cutaneous, mucocutaneous, and visceral). It exhibits variable clinical manifestations and is associated with extensive morbidity and even mortality. Proper diagnosis and identification of the parasite is critical in determining prognosis and appropriate treatment. Newer non-invasive methods of diagnosis with high sensitivity and specificity have been developed. Treatment of leishmaniasis is challenging, as the drugs used for treatment are toxic and poorly tolerated. Additionally drug resistance has been reported in many areas as well. Co-infection with HIV poses a major problem and increases risk of leishmaniasis associated mortality. Currently, leishmaniasis is not a vaccine preventable disease.

Keywords: public health, tropics, leishmaniasis

INTRODUCTION

Leishmaniasis is a disease complex caused by a heterogeneous group of protozoan parasites of the genus Leishmania. There are more than 20 Leishmania species and 30

* Corresponding Author's Email: kamal.kamboj@osumc.edu.

phlebotomine sandfly species, which transmit the disease to humans [1]. Dogs, foxes, rodents, and a variety of other animals serve as reservoirs for the parasite. The parasite can also be transmitted between humans through blood transfusions and shared needles [2]. Leishmaniasis presents as three clinical syndromes: cutaneous leishmaniasis, mucocutaneous leishmaniasis, and visceral leishmaniasis. The disease is known to be associated with poverty, malnutrition, famine, population displacement, urbanization, deforestation, agriculture, poor housing, poor education, and lack of resources [3-6].

The disease not only affects the health of the patients, it hinders the socio-economic development of the area. The severity of the disease is increased in people co-infected with HIV often resulting in relapses and a higher mortality rate [7]. Clinical management of leishmaniasis depends on the species involved and severity of infection [8]. There are only a limited number of drugs available to treat leishmaniasis and these are too expensive and are associated with adverse reactions. The emergence of drugs resistance has further complicated the control of leishmaniasis [9, 10].

Epidemiology

According to the World Health Organization (WHO), more than 12 million people living in 88 countries are at risk of being infected with different species of *Leishmania*. Approximately, 1.3 million new cases and 20,000 to 30,000 deaths occur each year [1]. The true incidence and prevalence is probably much higher due to widespread under-reporting of the disease [11, 12]. Case reporting has increased due to the availability of improved diagnostic tests. The geographical distribution of leishmaniasis is limited to areas of natural distribution of the sandfly vector. The incidence of leishmaniasis is higher in Asia, Africa, and the Mediterranean basin (Old World leishmaniasis) than in Mexico, Central America, and South America (New World leishmaniasis) [1]. Women have higher risk of infection due to their greater exposure to places of sandfly habitat [1].

Cutaneous leishmaniasis (CL) is the most common form of the disease with 1 to 1.5 million new cases per year representing 50 to 75% of all new cases. About 95% of cutaneous leishmaniasis cases occur in the Americas, the Mediterranean basin, Middle East, and Central Asia [1]. Over two-third of new cases of CL occur in six countries: Afghanistan, Algeria, Brazil, Colombia, Iran, and Syria. Mucocutaneous leishmaniasis is most common in South America, especially in Brazil, Paraguay, Ecuador, Bolivia, Peru, Colombia, and Venezuela. Ninety percent of the cases occur in Brazil, Bolivia, and Peru.

Visceral leishmaniasis (VL) is highly endemic in the Indian subcontinent and East Africa.

An estimated 200,000 to 400,000 new cases of VL occur worldwide each year. Over 90% of new cases of VL occur in six countries: Bangladesh, Brazil, Ethiopia, India, South Sudan, and Sudan. VL is common in farming villages where houses are made of mud walls and earthen floors and cattle and human live in close proximity. Post kala-azar dermal leishmaniasis (PKDL), a sequel of visceral leishmaniasis occurs mainly in East Africa and the Indian subcontinent [13]. The geographical distribution of different forms of leishmaniasis is presented in Figures 1-4.

Figure 4. Geographical distribution of Old World cutaneous leishmaniasis due to *L. major*. (Adapted from 1 with permission from WHO).

PARASITE

The leishmaniasis are caused by about 20 species pathogenic for humans belonging to the genus *Leishmania*. The parasite has two distinct stages in its life cycle, amastigote and promastigote. The amastigote stage, also known as Leishman-Donovan body, is found in the

reticuloendothelial cells of the mammalian host. These are small, round, or oval, measure 3-5 μm , and contain a large nucleus and a small kinetoplast. The promastigote stage is found in the insect vector and measures 15-30 μm in body length, and 1.5-3.5 μm in width, and contains a large centrally placed nucleus and a kinetoplast located near the base of the flagella.

VECTOR

Leishmania is transmitted by the bite of a small 2-3 mm long, hairy, sand-colored insect vector, the phlebotomine sandfly. Some 30 of the 500 known phlebotomine species have been identified as vectors of the disease [1]. The phlebotomine sandfly is found throughout tropical and temperate regions of the world. Only the female sandfly transmits the parasite. The sandfly gets infected with *Leishmania* parasite when it sucks blood from an infected human or suitable mammalian host. Inside the sandfly, the parasite transforms to the promastigote stage in about 4-21 days. The sandflies live in shaded microhabitats, are most active from dusk to dawn, and have a short flight range [14].

RESERVOIR

Leishmaniasis can be broadly grouped into two broad categories according to the source of human infection. In the zoonotic form, wild animals or domestic animals serve as reservoirs, while humans serve as reservoir hosts in anthroponotic leishmaniasis. Common reservoir hosts include dog, fox, sloth, cat, opossum and many others [15]. Human beings are directly involved as a principal reservoir host in VL caused by *L. donovani* and CL caused by *L. tropica* [1].

LIFE CYCLE

The infected sandfly during its blood meal regurgitates the promastigotes into the subcutaneous tissue of the human host [16]. These promastigotes are rapidly taken up by the mononuclear blood cells at the site of the bite where they begin to multiply and infect other cells and tissues. Once inside the macrophages, the promastigotes transform to the amastigote stages. The amastigotes multiply by binary division inside the macrophages, which eventually rupture releasing the amastigotes into the reticuloendothelial system of the host. These parasites are picked up by another sandfly during its blood meal to continue the life cycle. The amastigotes transform to metacyclic promastigotes in the midgut of the sandfly in 4-21 days, and are inoculated into the human host by the sandfly during the next blood meal. The life cycle is similar for different forms of leishmaniasis [17-19].

TYPES OF LEISHMANIASIS

Leishmania is known to cause three forms of disease in humans: cutaneous leishmaniasis, which is the most common form, mucocutaneous leishmaniasis, and visceral leishmaniasis, which causes disseminated disease. The form of disease depends on the species of *Leishmania* involved. Deviations from these main manifestations often exist which complicates or delays proper diagnosis.

CUTANEOUS LEISHMANIASIS

Cutaneous leishmaniasis (CL), also known as '*oriental sore*', is the most common form of this disease. The clinical features as well as the causative agents of CL vary by location. *L. tropica*, *L. major*, *L. aethiopica*, *L. infantum*, and *L. donovani* are the main species in the Eastern Hemisphere, while *L. mexicana* complex (*L. mexicana*, *L. amazonensis*, *L. venezuelensis*) and *L. viannia brasiliensis* complex are common in the western hemisphere [1]. CL causes a lesion in the form of a papule or nodule at the site of sand fly bite, usually on the exposed parts of the body [20]. These lesions appear within several weeks of exposure and may persist for several months or years.

Skin lesions are usually painless unless there is secondary bacterial infection. The skin lesions take on a variety of appearances and may resemble acne, warts, or psoriasis. The lesions of CL usually self-resolve within 6-18 month, leaving scarred tissues, which often becomes a cause of social stigma for the patients [21]. In patients with poor immune

response, the primary lesion may spread to form ulcers, plaques, and nodules over the entire body resulting in diffuse cutaneous leishmaniasis [22]. These nodular skin lesions often resemble those of lepromatous leprosy (Hansen's disease) and are difficult to treat. Unlike lepromatous leprosy, diffuse CL does show any nerve involvement.

MUCOCUTANEOUS LEISHMANIASIS

Mucocutaneous leishmaniasis (ML), also called '*espundia*', occurs most frequently in the New World. In ML, the parasite disseminates from the skin to the naso-oropharyngeal region leading to mucosal destruction. The development of ML is similar to CL and the two infections can occur simultaneously. ML is commonly caused by *L. brasiliensis*, *L. panamensis*, *L. major*, *L. tropica*, *L. infantum*, and *L. guyanensis* [1]. ML usually manifests several years after sub-optimally treated original cutaneous lesions. The initial manifestations of ML include persistent nasal stuffiness or bleeding, which may progress to ulcerative destruction of the naso-oropharyngeal mucosa [23]. ML caused by *L. brasiliensis* can often lead to disfiguring and is life-threatening. Often times, this disabling form of leishmaniasis can lead to the patient being rejected by the community. ML and CL can occur at the same time [24].

VISCERAL LEISHMANIASIS

Visceral leishmaniasis (VL) is the most complex form of the disease. It exhibits a broad spectrum of severity and disease manifestations. VL is usually caused by *L. donovani*-*L. infantum* complex. The incubation period of VL generally ranges from weeks to months. The infection may remain asymptomatic for prolonged periods and may become symptomatic in patients who become immune-compromised. The onset of the disease is usually gradual. VL in India is also referred to as 'kala-azar', which means 'black fever' or 'deadly fever' in Hindi, referring to darkening of the skin of the face, hands, feet, and abdomen. VL affects internal organs particularly the spleen, liver, and bone marrow. HIV co-infected patients may exhibit atypical manifestations such as, involvement of gastrointestinal tract and other organ systems [1].

VL is associated with fever, malaise, weight loss, anorexia, and discomfort in the left hypochondrium.

Non-tender splenomegaly with or without hepatomegaly, anemia, pancytopenia, high protein level, and low albumin level with hyper-gammaglobulinemia are usually seen. About 10% of VL cases develop lesions, which are initially present on the face, but may later spread to other parts of the body. These skin lesions may be macular, papular, and/or nodular in nature. This condition is known as post kala-azar dermal leishmaniasis (PKDL). It may also affect the conjunctival, nasal, oral, and genital mucosa. PKDL occurs almost exclusively in patients with visceral leishmaniasis caused by *L. donovani*; it is rare in cases caused by *L. infantum* [25]. PKDL patients do not have fever and the physical examination is usually normal [26, 27].

DIAGNOSIS

Clinical history plays an important role in the presumptive diagnosis of leishmaniasis in patients who live in or have visited areas endemic for the disease. However, signs and symptoms alone may not be enough to differentiate the condition, especially in areas where several other infectious diseases are prevalent. Clinical symptoms of CL may mimic other skin conditions such as, mycobacterial ulcer, leprosy, and skin cancers. Similarly VL may resemble malaria, schistosomiasis, or other systemic infections [8, 20]. Definitive diagnosis is essential to initiate treatment, which varies with the species of *Leishmania* involved. Visualization of amastigotes in the form of Leishman-Donovan bodies in Giemsa stained biopsy smear or aspirates by light microscopy is the classical confirmatory test [8, 28].

Specimens of choice in the case of CL include scrapings, fine needle aspiration, or biopsy of lesions. Parasites are scarce in ML due to strong local reactions; therefore, parasites are not commonly detected in dental scrapings or mucosal granuloma biopsy. In the case of VL, microscopic detection of parasites splenic aspirates is still considered the reference standard with sensitivity exceeding 95% [1]. However, bone marrow aspirate, liver, lymph node, and whole blood or buffy coats are preferred specimens as splenic aspiration can be associated with life threatening hemorrhage [1]. The sensitivity of bone marrow smear is about 60 to 85% [1]. Diagnosis of PKDL can be made by examination of slit-skin smears or samples obtained from nodular lesions. Culture of parasite can improve the sensitivity of detection of parasite, but leishmania culture is rarely needed in routine clinical practice [29].

Serological tests have been employed for the diagnosis of leishmaniasis [30]. A direct agglutination test (DAT) and rK39 dipstick test have shown promise under field conditions but exhibit variable sensitivities in different areas of the world [30, 31]. Antibody detection tests have inherent limitation of not being able to differentiate between current infections from past exposure to the disease. Further, these tests have limited value in case of CL and ML due to inadequate antibody response in these patients. A latex agglutination test (KAtex), which can detect polypeptide fractions of 72-75 kDa and 123 kDa in the urine of kala-azar patients, has shown high sensitivity and specificity [32-35].

Isoenzyme analysis has been employed to characterize the parasite to the complex and sometimes to the species level. However, the technique is cumbersome, time consuming, need technical expertise. There is also a lack of standardization among laboratories and incomplete correlation with the results [1, 36].

Molecular methods namely PCR and DNA sequencing have been employed for detection of parasites directly in biopsy samples overcoming the need of culture organism [28, 37-40]. PCR based methods can be used to monitor the response of anti-leishmanial treatment or to rule out latent infection when the parasite load is very low [41]. The widespread use of molecular diagnostics is still hampered by the requirements of substantial laboratory infrastructure, technical expertise, and cost [42-45]. Recently, a SMART Leish PCR has become available for the rapid diagnosis of cutaneous leishmaniasis even when the parasites in the skin are so low that microscopy and culture results will be negative at day 30 [46]. This test was developed in partnership amongst the Walter Reed Army Institute of Research (WRAIR, USA), the Army Medical Research and Materiel Command (USA), and Cepheid USA [47].

TREATMENT

Leishmaniasis is a treatable and curable disease. However, any chemotherapeutic intervention warrants proper species identification and ascertainment of any concomitant infections [48, 49].

Treatment needs to be individualized and may vary with the type of *Leishmania* species, severity of the disease, and other host factors namely age, sex, and immune status [50-52].

CL lesions usually resolve without any pharmaceutical intervention. However, treatment can speed healing, reduce scarring, and decrease the risk of mucosal dissemination and relapse of skin lesions. Relapse has been noted in patients clinically cured of leishmaniasis. Thus follow-up smears and cultures are recommended 1 to 2 weeks post therapy. Non-drug options include cryotherapy (with liquid nitrogen), thermotherapy (use of localized current field radiofrequency heat), and surgical excision of lesions. ML does not resolve spontaneously and it is very difficult to treat [52]. Treatment is usually unsuccessful unless started very early when the disease is mild. Full-blown cases may need plastic surgery to repair skin damage.

VL represents a severe form of disease and requires the use of effective systemic therapy. The prognosis of untreated VL cases is poor with mortality rate as high as 75% to 95%. Adequate nutrition to enhance the immune status in VL patients is important to reduce adverse reactions. There is limited evidence for the efficacy of PKDL treatment. The prognosis may depend on the severity of the condition and the duration of symptoms prior to initiation of treatment [53].

ANTILEISHMANIAL DRUGS

Pentavalent Antimonials

Sodium stibogluconate and meglumine antimoniate have been standard first-line medicines in most parts of the world (>90% overall cure rate) [1, 54]. However, drug resistance is becoming a major concern in India and Nepal [9]. Initial treatment of VL includes a daily injection of 20 mg/kg body weight of Sb(V) for 10-20 days [1]. These compounds may be administered intravenously, intramuscularly, or may be injected directly into the lesions. Common adverse effects include anorexia, vomiting, nausea, abdominal pain, malaise, myalgia, headache, and cardiac conduction defects. Given that substandard medicines can cause severe toxicity and death, the quality of pentavalent compounds should be assured.

Miltefosine

Hexadecylphosphocholine (Miltefosine), an oral alkylphosphocholine analog, is the first effective and safe oral agent for treatment of all forms of leishmaniasis. It also shows efficacy in refractory disease and in HIV patients suffering from CL and VL. Miltefosine is teratogenic and contraindicated in pregnant women. Nursing mothers should be advised not to

breastfeed during the course of treatment or for 5 months thereafter. Adverse effects with miltefosine include anorexia, vomiting and diarrhea, skin allergy, and renal insufficiency [55-57].

Amphotericin B Deoxycholate

Amphotericin B is a polyene antibiotic. A test dose of 1 mg, given by infusion, is recommended, followed by a full dose 4-6 hours later. Amphotericin B deoxycholate given daily or on alternate days by IV infusion in 5% dextrose for 4 hours at a dose of 0.75-1.0 mg/kg per day for 15-20 doses was 99% effective in India [1]. Infusion reactions include fever, rigor, chills, nephrotoxicity, hypokalemia, and myocarditis. Treatment should be given in hospital to allow continuous monitoring of patients. Lipoid formulations of Amphotericin B (liposomal amphotericin B, amphotericin B lipid complex and amphotericin B colloidal) are less toxic and require only 5 to 10 days of treatment or even as a one stat dose [58-62]. Mild infusion reactions (fever, chills, and rigor), transient nephrotoxicity, or thrombocytopenia are occasionally seen [1].

Paromomycin

Paromomycin, an aminoglycoside antibiotic, is usually administered intramuscularly and has been used for VL and CL. A dose of 15 mg/kg paromomycin sulfate (11 mg base) for 21 days gave a cure rate of 93-95% in VL in India [1] The efficacy was 85% in East Africa at an increased dose of 20 mg/kg (15 mg/kg of base) per day for 21 days. Topical paromomycin with methylbenzethonium appears to be more effective for treatment of ulcerative lesions due to *L. major* or non-ML associated Central American species [63].

Azoles

Oral ketoconazole, fluconazole, itraconazole have variable efficacy in treatment of leishmaniasis. Their use is limited to specific circumstances depending on geography and parasite species involved [64].

Pentamidine

Pentamidine isethionate is an alternative parenteral treatment for cutaneous leishmaniasis. Severe adverse effects including drug-induced pancreatitis leading to diabetes mellitus, dysglycemia, hypotension, hyperkalemia, myocarditis, and renal toxicity have restricted the use of this drug for treatment of *L. guyanensis* infections acquired in the Guyanas [65-67].

The treatment regimen should follow national and regional guidelines, if applicable, and treatment should be given under the supervision of trained medical personnel. Detailed information on the treatment of the various forms of the disease by geographic location is

available in the WHO technical report series 949 on the control of leishmaniasis [1]. Resistance to pentavalent and other antileishmanial drugs has been reported in various geographical regions [68-71].

PREVENTION AND CONTROL

Vaccine will be the ultimate tool for eliminating leishmaniasis. The development of a safe, effective, and affordable antileishmania vaccine has become a critical global public-health priority. Insufficient knowledge of parasite pathogenesis and the complexity of immune response have made it difficult to develop an effective vaccine for leishmaniasis. Both live attenuated as well as recombinant vaccines approaches have failed to generate protective response [72-74]. Vector and reservoir control can help block the transmission of the parasite [75]. Thus, no single method of intervention is likely to be successful in the control of the disease. The most common preventive measure is to avoid the bite of the sand fly [76, 77]. Simple precaution measures include the use of protective clothing (long sleeves, long pants, socks) and use of insect repellants containing N,N-diethyl-m-toluamide (DEET).

Residual insecticide spraying of houses and animal shelters and use of fine-mesh bed nettings impregnated with insecticides such as permethrin or deltamethrin have been tested with success in endemic areas [78]. Reservoir control is very difficult. Pyrethroid-impregnated collars have been used to prevent infections in canines [1]. These measures when implemented collectively can help to manage this complex and neglected disease [79]. Preventive health education in endemic areas can play a major role in the prevention and control of this leishmaniasis. New diagnostic tools and treatment strategies need to be made available in regions where the disease is prevalent. Remote sensing and geographical information systems can be used to investigate the large-scale distribution and risk factors of the disease.

ABSTRACT

As the world witnesses massive ongoing migration waves, numerous health and health care challenges arise as migrants venture out to new areas of residence. Among other concerns is migrants' access to health-care services which could be hindered because they fear authorities, encounter bewildering cultural and linguistic factors, have poor knowledge of the local health system, or simply are denied access to healthcare. Mostly, migrants face issues of mental health, chronic illnesses and infectious diseases. The response of healthcare agencies, NGOs and individual healthcare providers reveals a widespread inability to respond effectively and a lack of standard guidelines to address the issue. This chapter seeks to review the interplay between the phenomenon of migration and corresponding response from health care establishments, and to critically analyze the challenges posed by migrant crises and its implications for the future of public healthcare. Finally, a strong emphasis has been put on recommendations and appropriate responses have been suggested to tackle the problems associated with migrants to foster better healthcare for common welfare.

Keywords: migrants, migrant crisis, public health

INTRODUCTION

As has been observed in many studies, health related inequalities can be better understood and explained in relation to socio-economic status. Although the decision to migrate is sometimes a personal one and based on an individual's motivations, there are structural causes that need to be considered that are beyond an individual's or even entire population's control; environmental, economic, political, social and even religious circumstances such as wars, deprivation, persecution and social unrest can lead to voluntary or forced migration [1].

The term "refugee" carries substantial connotations that vary from very positive to absolutely negative. In this work, all who move from one country to another will be labelled migrants regardless of the reason they emigrated. A proposed classification of migrants by researchers [2] suggests that migrants should be classified into two distinct types: one which is based on free choices and individual opportunities, and a second that includes forced migration as part of large population movements resulting from marked economic, political or social inequalities. As observed in the previously mentioned study [1], the scope of the problem is difficult to assess accurately since by definition, many so-called "undocumented" migrants attempt to hide from the authorities or even from agencies that are designed to help them specifically since they fear deportation or incarceration. Even if migrants do register in one country, they may simply be en route to a third country where they do not register. Although the poor, displaced migrants are most often the subject of daily reports on the "problem," there are also well-educated, talented migrants who create a brain drain in their homeland as they move from poorer nations to richer nations that have more opportunities. These "highly skilled" migrants bring their own issues with them for public health [1].

Several studies done on Hispanic immigrants [2] in the United States found that they often are in better health than the native population of the destination country; this health advantage is known as "healthy immigrant effect," which is a protective effect of migrants' healthier lifestyle, diet and strong social bonds. Unfortunately, this health advantage is lost with time and in spite of socio-economic improvements due to the process of "acculturation," the assimilation of the dominant culture. Also, it can be noted that there might be a self-selection factor since normally only younger, healthier people might emigrate, who have a better level of health than the general population in their home country at first.

This decline in health can also be partially understood in the context of the living conditions of those immigrants. Despite socio-economic improvements in the destination country, accumulated less privileged socio-economic conditions both in the country of origin and the place of destination attribute to the lower health outcomes for those individuals from poor countries, as well as continuous exposure to hardships and discrimination which all are considered as mechanism of inequality. Adaptation to a new life, legal constraints, geographical distance to the country of origin, economic hardships, as well as loss of social status, separation from friends and relatives, often effects of a forced migration, are all considered barriers for migrants leading to health-related problems and inequalities [2].

HEALTH-CARE CHALLENGES FACED AS MIGRANTS ENTER NEW BORDERS

Migration occurs in waves, and because of the current large number of migrants attempting to reach Western Europe and the United States, political involvement has grown considerably [3]. Whenever war erupts, natural disasters emerge, or persecutions take place, natives are forced to flee their homelands to a safer country as they attempt to pursue opportunity elsewhere [4]. Between the 1880's and the 1980's, there has been a mix of migration waves within the United States alone, involving many Arab immigrants from 22 countries. The migration of immigrants progressed and continued throughout the years in three consecutive waves post World War II and after the passing of the Immigration Acts. Despite their goal to come to America for a better life, there was a high rise in cultural and ethnic tension owing to interactions with the white majority, just as had happened earlier with Polish, Irish and Italian immigrants in the USA [3]. Since World War II, Arabs have been deserting their motherlands for reasons such war, terror, and the pursuit of happiness [5].

This was just the early start of recognition of the health disparities presented for Arab Americans that continued to develop as a result of social, economic, political, and even legal factors [3]. According to the International Organization for Migration (IOM), about 800,000 migrants crossed the European border in 2015 alone [5]. In one year, hundreds of thousands of people have fled their homelands and migrated to Europe. These migrants have usually come from countries and areas such as Libya, Eritrea, Iraq, Africa, Middle East, Syria, and South Asia, migrating in order to pursue a promising and peaceful life for themselves, their families and descendants [5]. This massive influx has created a complex situation, especially in the European Union, as the Europeans attempt to deal with this immigration crisis [5].

According to the Global Commission on International Migration (GCIM), there are approximately 200 million international migrants in existence, the majority of whom (60%) have fled to developed countries [6]. International migration is one of the most politically-highlighted issues of recent times. Global policy-makers often raise this concern since it leads to cultural, social, and economic burden on the migrants and host countries. Both the host countries and the countries of origin are impacted economically [6]. The countries of origin experience a serious "brain-drain" as they lose their most valuable of people, who are highly educated and skilled professionals, which influences the supply and the quality of fundamental services in the homeland. The IOM states that 300,000 professionals from Africa are currently working and living in Europe and the United States [6]. The host countries are thought to believe that immigration leads to fewer jobs for their own citizens, lower wages, and conflicts among ethnic groups, ideal institutions, and distortion of the local community's identity. However, there are also benefits in gaining experienced professionals and educators, such as cultural enrichment and different ways of approaching problems [6].

The current migration crisis is a major issue spreading across several countries. Due to acts of violence in their homelands, over 4 million Syrians have fled the country. Additionally, over 4 million Iraqis have been displaced, either internally or as international migrants [7]. Many challenges arise when migrants venture out and are introduced to a new area of residence. Some major concerns are mental health, and chronic and infectious diseases introduced by refugees unfamiliar in the host country. The notion that migrants indeed disrupt the health system of a country is not astounding. Unfortunately, not much has been done to

highlight the importance or scope of this issue. On the other hand and despite the general perception, there have been reports from the WHO stating that there is no systematic association between infectious diseases and migration, and the risk of transmitting infectious diseases is extremely low [8].

Another main concern is simple access to healthcare. Many of the refugees are unable to effectively access health care because they fear the authorities, face substantial cultural and linguistic barriers, have poor knowledge of the country's health system, or are simply being denied access. Of course, there are differences among different groups of migrants based on cultural and life-style practices. Disparities exist among migrants due to high prevalence of risk factors such as sedentary lifestyles, bad habits of social smoking, hypertension and other illnesses, and mental stress from the effects of racism and discrimination [9].

According to the WHO, Europe is currently tending to a wide range of health problems of newly arrived refugees including accidental injuries, burns, hypothermia, cardiovascular problems, gastrointestinal illnesses, pregnancy/delivery complications, hypertension, and diabetes. Women further are faced with problems such as violence, sexual and reproductive health, maternal health, and child health. Migration adds to the burden of illnesses and health-harming habits of people these European countries are faced with such as; reproductive health problems, psychological disorders, nutrition disorders, newborn mortalities, drug abuse, alcoholism, and violence [8]. A high number of children are vulnerable to respiratory infections and gastrointestinal manifestations, due to their crowded unsanitary living environments [8].

Along with the increasing levels of illnesses, a high number of accidental deaths have occurred during these migrations. This number has been estimated to be as high as 3,100 in less than one year in 2015 among migrants crossing the Mediterranean Sea, who are believed to have either died or gone missing at sea, according to the United Nations High Commissioner for Refugees (UNHCR) [8].

With regards to infectious diseases, a number of factors influence the dispersions of microorganisms. These include population movements, commercial globalization, and environmental changes [10]. However, as previously stated, infectious diseases and migration have no link. For example, leishmaniasis, not normally found in Europe, cannot be transferred among individuals and is highly treatable. Furthermore, the chances of the host population of acquiring infections from the migrants' native lands such as Ebola, Middle East Respiratory Syndrome (MERS), or the Marburg and Lassa viruses; are tremendously low. Other infectious diseases similar to tuberculosis (TB) are not easily transmissible, unless there is an active infection. In fact, the estimated rates of TB transmissions are only 39 per 100,000 individuals in Europe alone [8].

Whether it is a security or an economic concern, migration has put Europe in a situation necessitating changes in their migrant policies for better strategies [5]. These strategies include: steps for ensuring ordered and effective migration policies in order to prevent people from being exploited by recruiters, traffickers and agents, realization of the fundamental human rights of migrants, and avoidance of cultural and social conflicts [5].

PROTECTED BY GLOBAL LAWS, THREATENED BY LOCAL POLITICS

The Constitution of the World Health Organization (WHO) of 1946 was the first to establish health as a human right at an international level. Just like all other human rights protected by international instruments and national constitutions and legislations, health is a human right whose protection and fulfilment is assumed by states. They ought to protect individuals and groups from undue interference with the enjoyment of this right, and take positive steps to ensure the realization of the right to health.

The International Covenant on Economic, Social and Cultural Rights (ICESCR) also establishes the “right of everyone to the enjoyment of the highest attainable standard of physical and mental health” in its Article 12. It also makes it clear that states are to exercise all rights including the right to health “without discrimination of any kind as to race, color, sex, language, religion, political or other opinion, national or social origin, property, birth or other status.” in Article 2.2.

Governments are required by international law to protect and promote the health of every individual within its territory regardless of their socio-economic, political, cultural, legal background or other status. Therefore, migrants are protected by international human rights law. In reality however, provision of health to migrants is a challenging task. Countries witnessing the inflow of migrants are usually torn between the willingness to help migrants and concerns for health safety of the native population. Public health policies involve prioritizing tasks and problems that require more attention. This may open the door for discrimination towards a few, thus violating the non-discriminatory nature of the laws protecting health rights. Public health policies may sometimes allow countries to limit health rights of certain individuals and groups in the name of protecting the health of the larger public.

Figure 1. Examples of the linkages between health and human rights (from the World Health Organization) (www.who.int/hhr/HHR%20linkages.pdf) (email approval for usage acquired from WHO).

Migrants, due to their fragile state of affairs, are often pushed into extreme situations that threaten their basic needs and rights. Through their migratory process, they may witness violations of several rights including rights to social security, adequate housing, clean food and water, work and the right to seek and receive information. An interdependence has been demonstrated between the right to health and other human rights (Figure 1). Several rights cannot be preserved without realizing the right to health. Similarly, with the violation of other rights, the fulfilment of the right to health becomes tricky. For instance, migrants are usually forced to live in unhygienic and unsafe conditions, with limited access to clean food and water. These factors pose a serious threat to their health, and to the ultimate realization of their right to health.

TAKING ACTION: THE RECOMMENDATIONS

Introduction

Migrant health is a major issue now unfolding as a crisis, posing serious challenges to public health. Increasing concerns related to the management of incoming migrants are based on the priorities of the governments in question not the migrants themselves. Thus, processes like registration, integration into the job market, geographical allocation, etc. tend to overshadow the basic needs of the migrants, healthcare being an essential one.

It needs to be realized that migrants being a diverse group might be migrating for varied reasons like better pay or a better life for their children or more pressing concerns like loss of life when forced out of their homes by wars and political instability. As a result, migrants often arrive with few resources. For many migrants, health is the only asset they possess. Unfortunately, their health status can be severely compromised by a wide range of health-determining factors at home, in the host countries, and during travel. It gets only worse for those entering a country illegally as they are forced to avoid the public spotlight. This scenario directly hampers the migrant's willingness or ability to seek medical care thus creating a huge crisis.

Further, there is a wide variability in how each country handles migrants with regards to the health care services different migrant groups are entitled to. Undocumented migrants are often forced to stay out of the public spotlight and avoid seeking medical attention even for serious debilitating ailments from fear of being arrested, prosecuted and deported. Also, the unpredictable distribution of work amongst NGOs and governments adds to the chaos and the complexity of the situation.

Naturally, language and social barriers can strongly hinder migrants' access to healthcare. On one hand, the attitude of the local population causes problems for migrants who have reported to face discrimination and harassment at clinics and hospitals. This problem is further compounded by the public's anti-migrant sentiments and lack of empathy and consideration towards migrants, holding the belief that the migrants are living on "the taxpayers' money." On the other hand, migrants' attitudes can also contribute to the crisis as those coming from poor underdeveloped countries tend to have a weak understanding of the healthcare system (especially primary) and fail to efficiently utilize the healthcare services

they're offered. This can also be contributed to by their pre-existing social, cultural and religious notions they may have regarding health and wellbeing.

While there may be several lines of action that can be taken to tackle the issue of migrant health, progress is hampered since so far no one has been able to statistically explain the implications of rising migration rates for public health and to determine a "common minimum" of healthcare services that must be provided to all migrants regardless of their social, cultural, demographical and legal background. Without providing access to clean and safe food, water and housing, we run a risk of having our efforts to promote health and provide healthcare services negated by other factors that greatly impact health.

Particularly with regards to the development of personalized medicine in healthcare, migrant health should be a pressing concern. Given that migrants are a diverse group, from varied cultural and socio-economic backgrounds, as well as having different health goals and challenges, their wellbeing is crucial to ushering in an era of personalized medicine. What is currently being done is, instead of assessing the underlying factors impacting migrant health and focusing on the unique health needs of the subgroups within the migrant population, emphasis is being put on making healthcare as widely accessible as possible. Thus, our focus needs to be shifted from quantity to quality with how we treat migrant populations at healthcare centers being our main concern and not how many of them we treat.

Therefore, the provision of efficient primary health care should form the foundation of migrant health policies and programs. Early detection, treatment, education, and relevant preventative measures can go a long way in improving migrant health conditions and standards, thereby reducing their vulnerability towards more complex diseases. This approach is also cost-effective in the long run, as it reduces incidence of more complicated diseases and thus reducing the burden on emergency care, which is substantially costlier than primary health care. There is also a need for a multi-faceted approach, with attention to other health-determining factors like food, water and living conditions. On a political level, closer coordination between NGOs and governments is needed.

In this section, we will discuss major recommendations and steps that should be taken to streamline the management of migrants to ensure the delivery of good quality healthcare to them, while addressing underlying factors contributing to the common problems and challenges migrants face regarding their health and their access to healthcare.

Screening and Its Importance for Migrant Health

The ECDC (European Centre for Disease Prevention and Control) defines screening as 'the systematic practice of medical examination, involving laboratory or other diagnostic testing, to search for and identify cases of a specific infectious disease in a target population'. Many types of migrants go through mandatory health screening in countries of origin in order to receive a visa and recommended screening upon arrival in the host countries. They are screened for a wide range of ailments like infectious, parasitic and sexually transmitted diseases and chronic illnesses, with tuberculosis being the disease most commonly tested for. Experts state that screening can help identify new and asymptomatic cases of infectious diseases, and help in prevention and early detection of certain diseases, thus reducing long-term burden on public health.

At a time where anti-migrant sentiments are on the rise, where migrants are being blamed for causing diseases, with newspaper headlines demanding migrants be sent back home, it becomes inevitable to ask the question- How much of a threat do migrants really pose to public safety? There is no factual evidence supporting a possible increase in risk of infectious diseases within the local population caused by migrants. A study on tuberculosis in migrants moving from high-incidence countries to the UK found that migrants posed a negligible risk of onward transmission, but were at risk of developing active tuberculosis after arrival, with incidence peaking in the fourth year after arrival [11]. With a pre-entry screening program along with timely treatment of the latent infection, the incidence could be significantly reduced.

How effective or cost-effective is screening in newly arrived migrants? The issue remains contentious. Studies report that screening for infections like tuberculosis and Hepatitis-B can be implemented cost-effectively, thereby helping identify migrants with latent infections and potentially reducing related morbidity and mortality [12, 13, 14]. The implementation and practices related to screening programs vary among countries, as there is no “one-size-fits-all” approach. It is important to determine where, when and for whom screening programs can be most useful and effective.

The WHO recommends against obligatory screening of migrants (including refugees), due to the lack of clear evidence of benefits. Moreover, WHO states that it has the potential to cause fear and anxiety within migrants and the local population. Nonetheless, WHO does recommend that health checks and good-quality healthcare be provided to migrants. Human rights and the dignity of migrants must be highly respected, and screening results should not be used to justify the ejection of migrants from the country.

Nevertheless, screening results serve as valuable information for public health authorities in structuring health programs and policies to better meet migrants’ needs. It is encouraging to see that a variety of actions are being taken by countries on the basis of screening results, including provision of treatment upon disease detection [12]. Unfortunately, with poor follow-up care and low treatment completion rates, screening programs can potentially be rendered ineffective. Therefore, along with improving screening programs, it is crucial to devise strategies to facilitate migrant access to a full range of healthcare services, as well as development of treatment, vaccination and health awareness programs.

Unhygienic living conditions, contaminated water and food and poor sanitation are conditions that favor the spread of communicable diseases. Therefore, alongside the provision of healthcare services for treatment of illnesses, steps should be taken on a preventative-level by ensuring the quality of other health-determining factors such as food, water and living conditions. Nutritious food and clean water must be made widely and easily available.

Orienting Migrants to the Country’s Healthcare System: Identifying Barriers, Needs and Requirements

As mentioned earlier, migrants come from diverse cultural and socio-economic backgrounds. Migrants coming from underdeveloped countries may have a poor understanding of the host country’s healthcare system. Pre-existing social and cultural notions can also influence how migrants perceive healthcare services. Along with this, language

barriers can immensely impact the quality of health care migrants receive. These challenges are also taxing for healthcare providers, who feel incapable of addressing the migrants' illnesses in a holistic fashion, and may eventually mold their approach to make their interaction with migrants simpler and shallower, to avoid dealing with more complex and "hidden" illnesses like mental disorders.

To ensure delivery of efficient and suitable health care to migrants, it is important to assess knowledge, cultural and language barriers towards healthcare in migrants, and identify other potential challenges as early as possible. On-arrival screening programs serve as an opportunity to assess migrant attitudes and perceptions regarding the healthcare system, and identify individuals who may need immediate care and attention. Vaccination status of migrations should also be assessed. It is preferable that migrants be adjusted into the primary health care system with minimal delay.

Also, there is a need to make healthcare services more culturally-sensitive for migrants. This can be done by setting up "migrant-friendly clinics," and recruitment of a culturally-diverse staff for medical centers that regularly deal with a large number of migrants. Language interpreters should be assigned to migrant groups, who would also be in close contact with healthcare authorities with the assistance of social workers. Due to previously reported poor quality and implementation of interpreting services [15, 16], there is a need to improve integration of interpreters into the communication chain between migrants and healthcare providers. However, it is also important to train the interpreters in health care language so that they can be effective in communicating often complex and culturally specific health information from migrant to the health care worker and vice versa. Also, another step in sensitizing medical staff towards migrants is to train them to work in a culturally sensitive way with patients with traumatic experiences, including women and girls who may have been victims of sexual violence.

Another innovative approach is to train a few people from within the migrant community on topics of health issues, healthcare services the migrants are eligible for, what to do when feeling sick and equip them with basic medical and clinical skills like first aid, basic life support and administering injections. This will positively influence the migrants' outlook on health and healthcare, as they see their fellow migrants putting in efforts for the betterment of health of the community. Orienting migrants to the host country's healthcare system and educating them about important health problems through seminars, workshops and other didactic methods is crucial in making sure migrants utilize the available health services efficiently and effectively.

Clearly, there is an urgent need to include migrants in more and more health impact assessments. A review found that only 14% of health impact assessments mentioned migrants in the evaluation, with only 2% mentioning them in the recommendations [17]. Health impact assessments help us improve fairness and justice in healthcare delivery by looking into unintended harms and allowing the maximization of benefits. This in turn assists decision-makers to develop efficient and effective health policies and programs. Relevant steps must be taken to facilitate the process of data collection, so that the migrants can be represented fairly during decision-making. Underlying challenges must be addressed, like social, cultural and language barriers, and apprehension of undocumented migrants towards data collection authority and procedures. Instead of mere descriptions of the situation, there is a need for more analytical studies and explanatory models to deal with the underlying causes and wide array of challenges faced by the heavily heterogeneous migrant population.

Mental Health: A Major Concern for Migrant Health

The issue of mental illnesses among migrant populations should be a pressing concern. There is sufficient evidence to suggest that some migrant groups are at a higher risk of developing mental illnesses than others. Migrants, especially refugees, experience several distressing events prior to, during and after their migration which have an immensely debilitating impact on their mental well-being. Underlying mental illnesses can influence presentation of physical health conditions, and can even reduce effectiveness of treatment. This translates into higher migrant health costs, and potentially social exclusion by hindering integration, educational success, and employment. This in turn gives rise to the perfect breeding ground for radicalization and organized crime.

The Committee on Migration and Health Challenges of the European Health Parliament in a paper [19] called for a focus on mental health when providing primary health care to migrants. They recommend the development of community-level programs, which would increase the number of healthcare recipients, and help lower healthcare costs usually incurred by psychiatric-healthcare models, involving individual consultations. Particular attention should also be paid to the more vulnerable group of minors, through the development of school-based programs. This will help address several challenges simultaneously: language and social barriers, integration difficulties, and mental health issues. They also recommend that mental health be given increased attention under the EQUI-HEALTH initiative launched by the European Commission and the International Organization of Migration, which currently focuses more on physical health. The EQUI-HEALTH initiative aims to facilitate exchange of best practices between member states and non-governmental organizations regarding migrant health. Besides this, the Committee also proposed a transparent cost-sharing mechanism amongst the EU Member States for the provision of free primary care to migrants. Sharing costs according to State size and wealth will help ease financial burdens and will allow for a more even distribution of migrants across the EU.

On the other hand, raising awareness about mental illnesses amongst migrants is equally important and they should be encouraged to consult a physician/therapist/social worker if they experience any psychological disturbance owing to trauma and stress. Therefore, a deep understanding of the individual's social, cultural and religious backgrounds and their influence on health is essential. A migrant population's cultural influences on their perceptions of health and disease must be explored as culture can profoundly affect how people perceive illness and how they interpret and react to symptoms. More importantly, people, especially from underdeveloped and developing nations often have culturally-oriented methods of dealing with mentally ill people. Some may first suspect a "demonic possession" or "witchcraft" in a person clearly showing signs of a mental disorder. Therefore, it is crucial that the aspect of cultural perception of illness is taken into consideration when treating migrants for mental illnesses. Inquiries must be made regarding the patient's adherence to prescribed treatment and usage of any alternative medical treatment like herbs, as they may cause drug interactions and side effects. Similarly, for other psychological treatments like psychotherapy to be effective, the underlying philosophical basis must be acceptable to the patient.

Yet another crucial aspect is that of communication. Effective patient-doctor communication is an essential aspect of treating mental disorders in migrants. Patients should be encouraged to use interpreters if they have a limited proficiency in the language(s) the physician knows. Although patients may seek help from family members and friends on this matter, studies have shown that professional interpreters can improve communication and increase the likelihood of asylum seekers disclosing psychological symptoms [20-23].

Further, social support is extremely crucial to facilitate the processes of integration and acculturation among migrants, and to help them manage stress. Feelings of isolation and alienation can be reduced by developing a social support system that allows migrants to network with individuals from the same ethnic and cultural backgrounds with a significant amount of experience living in the country. Ethnocultural community and religious institutions can play a major role in the migrants' adaptation to their new lives and integration into their new society, assisting them in dealing with personal, social, financial, educational and legal challenges. Presence of and networking with role models from the same background and a strong sense of ethnic pride can help migrants tackle issues of discrimination and racism [24].

Women's Health among Migrant Populations

As in any other humanitarian crisis, women form a particularly disadvantaged group among migrants. Especially for women from highly patriarchal communities, their inferior social status along with limited educational and occupational experience makes them susceptible to poverty, sexual violence and further forms of marginalization. Particularly, the sexual and reproductive health of women in migrant communities is considered a public health crisis. There is a dire lack of research data on the sexual and reproductive health challenges faced by migrant women and girls.

The need to make healthcare more culturally-competent for migrants also applies to women's health, making it important to understand the socio-cultural influences on the topics of sexuality, body and health, as well as addressing cultural and language barriers. It is important that migrant women and girls be provided with suitable maternal health care, contraceptive counseling and safe abortion services where possible, since many host countries impose their own restrictions restricting access to contraceptives and even outlawing abortion even for rape. HIV testing, treatment and counseling should also be offered. Information related to sexual and reproductive health should be made available and easily accessible.

Since education and counseling is a vital aspect of public health, raising awareness about common sexual and reproductive health problems, how to seek healthcare services and available financial assistance through circulation of information packages can increase effectiveness of current health policies. Programs should be developed to support improvements in the socio-economic conditions of migrant women and girls. This can be done by providing them with educational opportunities, vocational training and taking steps to eventually integrate them into the workforce.

The Plight of Undocumented Migrants (UMs)

Indeed, one of the biggest challenges of the migrant crisis has its roots in the complex heterogeneity that arises from factors such as age, gender, socio-economic background and legal status. Particularly evident is the disparity in the healthcare offered to migrants based on their legal status. Where refugees may be entitled for certain free health services in a country, asylum seekers may not. UMs (Undocumented migrants) are a group of migrants who often have had a restricted access to healthcare, and whose rights are often overlooked. Data on UMs and their health challenges is scarce, as most studies are directed towards care-seeking migrants. UMs face both formal and informal barriers to health, like social and language barriers, poor understanding of the healthcare system, fear of getting reported to the police and downrightly being refused treatment at healthcare institutions.

However, the ethical argument for providing healthcare to UMs is rooted into the humanitarian notion of “right to healthcare” regardless of one’s social, economic, religious, legal or political background. One of the biggest challenges for any country is reaching out to its UMs. Only 50% of the UMs in a study from Netherlands were found to know how to get access to medical care if in need [18]. With continuously harshening immigration policies, UMs feel threatened and do their best to avoid any contact with official authorities, including healthcare providers. UMs must be educated about the country’s healthcare system, what services are available to them, how and when to access them.

Although, no country wishes to be portrayed as an attractive goal for illegal migration, steps must be taken to ensure proper access to healthcare services for UMs. Looking at the variation in the implementation of healthcare rights of UMs, there is a need for standardization of guidelines and protocols. Otherwise, migrants’ access to healthcare will continue depending on the healthcare staff’s personal persuasions and personal interpretations of the ethical code. It has also been suggested that, with reference to the international healthcare law, access to healthcare should not be intertwined with an individual’s immigration status. Therefore, as WHO recommends, all refugees and migrants must have “full, uninterrupted access to a hospitable environment and, when needed, to high-quality health care, without discrimination on the basis of gender, age, religion, nationality or race.”

Migrant Crises: Political and Institutional Contributions and Responsibility

While some countries like Canada have opened their doors to migrants of all types, others have become more restrictive by limiting the inflow of migrants, increasing deportations and going even further by blocking relief efforts of other entities, including NGOs. The United States’ recent suspension of its refugee program at the start of the Trump presidency augurs ill for the health and wellbeing of disadvantaged migrants seeking a safe haven in the United States for at least the next four years.

It is high time global leaders work together in tackling the issue of migrant health, which is of worldwide interest. There is a dire need for global cooperation, now more than ever, to deal with the financial, social, legal and political implications of migration and challenges of migrant health. With the development of cost-sharing mechanisms, financial burdens can be evenly distributed amongst countries. Steps should be taken to rectify uncertainty revolving

around the legal status of migrants in several countries, and what healthcare services they are entitled to. It is also necessary that global leaders voice the urgent need for local societies to support migrants in all possible ways, reiterating the importance of the contributions migrants have made to their societies. Prominent social figures, like politicians, sportspeople and athletes, and figures from the music and movie industries should speak up about the issue of migration, migrant health and the rights of migrants. These actions can help deal with the current fear and anti-migrant sentiments prevalent in the general public.

In addition, coordinated collaborations between governments and international as well as domestic NGOs in the countries of origin and host countries are essential. This will facilitate the development of an integrated approach towards migrant health where the concerns of all parties involved are taken into consideration. The development of innovative healthcare that better accommodates the needs and goals of migrants can be facilitated through an extensive and coordinated collection of data on the most prevalent health challenges, current health status of the migrant population as well as other health determinants related to legal and socioeconomic factors. With a better understanding of migrant health challenges, healthcare providers can be trained through international partnership agreements to achieve desired healthcare outcomes efficiently and effectively.

The Role of Technology in Improving Healthcare Access and Delivery

Advancements in technology are driving a massive reform in the operational structure and organization of the healthcare industry. Technology can be the determining factor for migrant health and creating greater equity in the near future. As human lives are becoming more “electronic” and “internet-based,” hospitals and other healthcare-providing institutions have kept up by providing “e-services” to their customers. From checking prescribed medications to viewing MRI and X-ray results, those services can be accessed over the internet through web browsers and mobile phone applications.

Undoubtedly, telehealth is an area that should be actively integrated into the migrant healthcare system. It can help address cultural, social and geographical barriers that migrants face. Development of an electronic network for migrants would facilitate their access to healthcare services. Health and healthcare-related information in the form of guidelines, recommendations, reminders and protocols could be electronically delivered to migrants, cutting down the costs of printing brochures, pamphlets and booklets, and the workforce needed to distribute them.

It is worth mentioning that iamsick.ca has set an example in developing more intelligent telehealth. It is an innovative project that aims to develop health technology platforms that helps patients’ accessibility to find the healthcare services they are looking for. Users can search for doctors and other services like pharmacies and diagnostic labs near them. What is unique about iamsick.ca is that users can search for doctors who speak their language. This feature is especially valuable for those who don’t speak the local language and are facing social and cultural barriers in accessing healthcare. Migrants very often find themselves in similar situations, and technologies like iamsick.ca can immensely help them with their healthcare needs. Similar platforms could also assist healthcare providers with dealing with migrants and providing the best possible care.

Furthermore, many electronic applications and platforms have been designed to improve doctor-patient interaction, without the need of the physical presence of the doctor with the patient, by providing a safe channel of communication that allows sharing voice, picture, video and text notes to describe the medical problem to the physician allowing him/her to reply with proper medical management. These kinds of apps can be further utilized to overcome the lack of highly specialized doctors in complex situations.

Moreover, a sensible solution for the huge language barrier between migrants and healthcare providers is applications that help in the translation of health complaints and questions such as “AOK HealthNavigator” and “refugeespeaker.” Apps like these can provide efficient language assistance to patients in the absence of professional translators.

Medical record tracking apps such as Microsoft HealthVault, are electronic services that allow users to keep their medical records safe and up-to-date, and share them securely with healthcare professionals and people they trust. Having been around for a few years, these electronic services have a dedicated following, including people with chronic conditions who need to track daily health metrics, such as blood pressure, glucose, and oxygen saturation.

Electronic apps also can help in screening for medical problems, either through self-screening tests such as the ones for depression, or through scheduling screening, or even for screening conducted by authorities to detect serious illnesses requiring urgent intervention.

Disclaimer: The authors are not affiliated with any of the mentioned applications above in any way, nor are they being compensated by any of them)

CONCLUSION

With the international growth of the phenomenon of migration, migrant health challenges are gaining global significance in public health. Given that migrants are a diverse group from varied cultural and socio-economic backgrounds, as well as having different legal status, it has been observed that migrants’ health situations can be severely compromised by a wide range of health-determining factors at the country of origin, in the host countries, and during travel. These compromises range from accidental injuries, infections, to serious chronic medical conditions.

Alongside early detection, treatment, and relevant preventative measures, we recommend ensuring the quality of other health-determining factors such as food, water and living conditions, thereby reducing migrants’ vulnerability towards more complex diseases. This approach is also cost-effective in the long run, as it reduces incidence of more complicated diseases and thus reducing the burden on emergency care, which is substantially costlier than primary health care.

The current emphasis of health care provided to migrants is being put on making healthcare as widely accessible as possible. However, this should not deviate the attention from devising health policies and programs that provide an efficient access to primary health care of an acceptable quality to all migrants in the host countries. In order to do that, all challenges for health care access should be dealt with effectively.

We recommend studying the current screening programs in addition to possible strategies that facilitate migrant access to a full range of healthcare services, as well as development of

treatment and vaccination programs. Moreover, we recommend a special focus on health education and awareness programs as well as orienting migrants to the host country's healthcare system, while providing them with all that they need to overcome the potential barriers for health care accessibility. Also we highlight the significance of health impact assessments for migrants globally in order to improve fairness and justice in healthcare delivery.

Furthermore, major concerns for migrant health such as mental health, should be dealt with carefully as there is an increased susceptibility of all migrants to have psychological problems, due to the unfortunate situations and stress they accumulate throughout their journey and residence in the host countries. Along with the typical solutions we highlight the role of the ethno-cultural community and religious institutions in the migrants' adaptation to their new lives and integration into their new society, by assisting them in dealing with personal, social, financial, educational and legal challenges.

Special care should also be given to a potentially vulnerable group in most migrant communities - women. This should be mainly through education, counseling and psychological support, keeping in mind that they are susceptible to poverty, sexual violence and further forms of marginalization. We believe that the utilization of innovative and creative solutions such as telehealth should be actively integrated into the migrant healthcare system, which would allow us to improve accessibility, outreach, and communication between migrants and health care providers. On a political level, closer coordination between NGOs and governments is needed.

In conclusion, it is clear that the lack of a personalized equitable system of healthcare has been responsible for compounding the health crisis among migrant populations. It is only through education, counselling and outreach efforts that these disadvantaged people can be helped. The key lies in setting up uniform medical guidelines and determining what basic medical facilities should be available to migrants irrespective of their status and to simultaneously train medical professionals to effectively respond to migrant health problems. Undoubtedly governments, humanitarian organizations and medical professionals will have to work together and develop methods for collecting data on the challenges faced by these migrants in order to facilitate the development of effective healthcare policies and systems addressing their health problems.

Chapter 517

NONVERBAL COMMUNICATION BETWEEN FINNISH AUTHORITIES IN ANIMAL DISEASE EMERGENCY EXERCISE AND IN PUBLIC HEALTH BORDER CONTROL MEASURES

Heli I. Koskinen*

Faculty of Social Sciences, University of Helsinki,
Helsinki, Finland

ABSTRACT

In Finland, contingency planning has been implemented among veterinary and public health authorities. Contingency plans have been developed for foot-and-mouth-disease, classical swine fever, Newcastle disease and zoonotic (transmissible between humans and animals) avian influenza as well as for other easily spreading animal diseases (African swine fever, Bluetongue, epizootic haematopoietic necrosis, infectious salmon anemia, viral haemorrhagic septicaemic, infectious haematopoietic necrosis). Detailed manuals of operations have been established by the Finnish Food Safety Authority Evira and the Regional State Administrative Agencies and emergency exercises have been organized for a real emergency situation. Alongside with continuous disease control, authorities have together organized additional random controls at the borders of Finland because Finland is free of dangerous animal diseases such as zoonotic rabies and echinococcosis (*Echinococcus multilocularis*), which are found in Finland's neighboring countries.

Those animal diseases, which must be reported immediately to the veterinary authorities have been listed in the animal disease legislation. Act on animal diseases 441/2013 stipulates that if the owner or keeper of an animal, butcher or anyone with contact on animals or a veterinarian other than the municipal veterinarian, suspects an outbreak of an animal disease that is notifiable according to animal disease legislation, he or she must report this to the municipal veterinarian or, failing this, to the regional veterinary officer. The municipal veterinary officer must report further to the regional veterinary officer, who reports the suspected outbreak to the Finnish Food Safety

* Corresponding Author's Email: heli.i.koskinen@helsinki.fi.

Authority Evira. In case of real disease outbreak, Evira as the central competent authority can request further resources from other services (police, rescue teams, fire brigade and veterinary students). These procedures are, however, strategic procedures written in legislative level far from the level of operations and real activity. For example, the flow of information between authorities can be better organized. Thus, in the context of communication studies, the aim of the current study is to clarify the nature of interaction between different authorities.

The main question of this study was what kind of nonverbal interaction can be revealed from interaction situations between a) veterinary authorities in emergency exercise, b) veterinary authorities in additional random controls at the borders. As a research material, media pictures from Google search engine were used and these pictures were analyzed by using nonverbal communication research method. Following the Google search with well-known three controls at the borders in 2016 and African swine fever emergency exercise in 2014 four pictures about communication situations were collected. Common background context and discourses of responsibility, control and fear were constructed. Between authorities, working in a focused manner with minimal facial expressions and gestures was mainly seen. The authorities looked at important documents rather than to each other. They were seriously involved. Cultural differences in organizations must be, however, included in a final conclusion. Different contexts in multi-organizational interaction should be respected and utilization of nonverbal communication studies should be expanded over the veterinary context.

Keywords: authorities, contingency planning, disease control, emergency exercise, public health, zoonotic

INTRODUCTION

In Finland, several authorities have prepared for outbreaks of animal diseases. Both the Finnish central authority, the Finnish Food Safety Authority Evira and the Regional State Administrative Agencies have their own contingency plans, which, along with other public health contingency plans, are part of strategic public health documents. Their goal is to protect the population against diseases, which can be zoonotic (transmissible between humans and animals) or which may result losses to domestic livestock production. In Europe, authorities are well prepared for outbreaks of avian influenza (Pittman & Laddomada, 2008). Intergovernmental organization World Organization of Animal Health (OIE) organizes international emergency exercises against avian influenza but also against most important animal diseases. In Finland, contingency plans against foot-and-mouth-disease, classical swine fever, African swine fever, Newcastle disease, avian influenza, Bluetongue and some fish diseases (epizootic haematopoietic necrosis, infectious salmon anemia, viral haemorrhagic septicaemia, infectious haematopoietic necrosis) are established. All of those diseases are combated by nature in the Finnish law on animal diseases.

As a part of their normal control and monitoring of animal diseases the Finnish Food Safety Authority Evira and the Regional State Administrative Agencies organizes national emergency exercises, in which veterinary authorities can participate in a simulation of a real disease outbreak and exercise the interaction between authorities. During the simulation, they can experience a legal definition of flow of information, which must immediately flow from a municipal veterinarian to a regional veterinary officer or to the Finnish Food Safety

Authority, or from the regional veterinary officer to the Finnish Food Safety Authority. In regional level, in addition to regular exercises in the Regional State Administrative Agencies between veterinary authorities, some random controls at the borders of Finland are organized. They are organized between veterinary and other authorities (customs) and these controls' goal is to prevent the spreading of foreign diseases (rabies and *Echinococcus multilocularis*) from neighboring countries Estonia and Sweden to Finland.

Strategic procedures written in legislation or contingency or preparedness plan are not same as the real operations in the field. Although preparation in European Union countries is at a good level in some parts of preparedness plans such as surveillance, planning, coordination and communication, maintenance of essential services, putting plans into action and public health interventions are inadequate (Mounier-Jack & Coker, 2006). It has been shown in some international health crisis - origin of animal diseases - that authorities are slow to respond or have no response at all, maybe, because of inadequate information flow between authorities (Uhlenhopp et al., 2004). The authorities may comply with different laws and orders (Amarasekara, 2007; Koskinen, 2012) and thus, work in different contexts. In emergency, different authorities work in the same field and they should play a same game. They should improve and know their roles and responsibilities (Bar-Yaacov, 2008) and their chain of command from authority to authority within and over the administrative borders (Jebara, 2004). In Bourdieu's words (1971, p. 161), they should be agents in objective social relations like players in the field.

Authorities are located in subfields defined by their different administrative levels. In these subfields, players have different forms of material and symbolic power (Bourdieu 1971, 1988). One critical point is competitiveness between sectors, services, professions and persons as well as different administrative locations (Busani et al., 2006). Different subfields create different contexts and different functionalist language use, discourses, which means that subfields have unequal (linguistic) power. It is, then, the network of objective relations between (linguistic, symbolic) positions - the field itself - that subtends and orients the strategies of authorities in a practical level (Bourdieu & Wacquant, 1992, p. 16). Meaning of action arises from interaction. It is interaction between "me" and "those other people" and it is transmitted by symbols (Mead, 1932, 1967). It can be linguistic interaction with symbolic characters of language or nonverbal communication with cultural gestures and facial expressions full of symbolic meaning (Mead, 1932). Interaction can also be participation in social environment, which is full of roles, norms and models of appropriate behavior (Bandura, 1986, p. 47, 49-50).

The study of discourse is usually confined to speech and writing (Parker, 1999, p. 1). However, some researchers go beyond of that kind of discourse analysis towards wider range of texts (Allbutt, Gray, & Schofield 1999; Durmaz, 1999; Russell, 1999). In these analyses, symbolic systems (visual media with visual text and physical settings) that are not usually thought of as textual are involved (Parker, 1999, p. 1). Nonverbal gestures, facial expressions, body positions, gazes, tone of voice, dressing and physical space are all involved because the word "text" can be any interaction unit full of meaning (Kress, 1995; Parker, 1999, pp. 3-4). Nonverbal behavior means dynamic and context-specific body information with high communicative potential (Burgoon et al., 2000; Guerrero & Floyd, 2006). Nonverbal cues may be important part of the verbal accounting process (Birdwhistell, 1970) and they are usually categorized by linguistic-like structural organization. Such a categorization, like well-known Bales' Interaction Process Analysis (1951) with its categorization of both verbal and

nonverbal acts, however, is questionable for the study of nonverbal discourse because of its pre-specified, ill-defined and discrete verbal categories (West & Zimmerman, 1982).

Regardless of the nature of communication - verbal or nonverbal - it is an activity and action of people. Theoretically, activity, action and operation can be defined at various levels (Elliot, 2007, p. 37). Activity describes the ability or capacity of an individual whereas action means concrete, practical doing. Operation is a larger and upper level of communication, which includes different forms of communication and interaction between actors. It is usually this operational level with which researchers are dealing when real action have been studied. Some previous examples from verbal and nonverbal studies at this operational level come from higher education field (Fahy, 2005; Hancock, 2004; Koskinen, 2010, 2011; Koskinen & Snellman, 2011). One study has been concentrated on nonverbal style in public and civic settings in Finland (Wilkins, 2005). In current study, the aim was to describe how social reality of Finnish authorities was constructed at operational level. It was realized that social phenomena are not the same across different situations with different times and thus, it was investigated what kind of nonverbal interaction was revealed in different co-operative situations. The aim was to describe the manner in which these situations were similar to each other and, respectively, how they differ from each other.

METHODOLOGY

In the context of Finnish circumstances and interaction between Finnish authorities, qualitative case study design was utilized. Four well-known cases were included: one was a veterinary emergency exercise (African swine fever 2014) and three were random border controls in 2016 in Finland (cities of Turku, Helsinki and Tornio). Rigorous qualitative case studies give researchers opportunities to investigate or describe phenomenon in context using a variety of data sources (Baxter & Jack, 2008). In this study, visual texts, media pictures, were used as research material. These four pictures were searched from internet by Google search engine by using Finnish words (with their English translations in parenthesis) 1) "aluehallintovirasto (Regional State Administrative Agency) tullit (Customs), Elintarviketurvallisuusvirasto Evira (the Finnish Food Safety Authority Evira)," 2) "Länsisatama (West Harbour) tehovalvonta (power control) aluehallintovirasto (Regional State Administrative Agency)," 3) "Länsiraja (West border)," 4) "eläintauti (animal disease) leviäminen (distribution) estäminen (inhibition)." Final data sources consisted of internet-based media pictures from rural newspaper *Future of the countryside* (Maaseudun Tulevaisuus in Finnish), *Evening Journal* (Iltalehti in Finnish), a national daily newspaper, *Helsingin Sanomat*, and news channel Yle (Finnish news channel of public areas). In addition to different media sources, also different authorities in different media texts were introduced.

In case study design, interpretative paradigm can be preferred over traditional (normative) organizational research paradigm (Fitzgerald & Dopson, 2009). This framework was taken seriously when the media pictures from the life of organization and authorities were analyzed. Instead of measurement of frequencies of events and their consequences, the storytelling perspective was assumed. These pictures can tell a story, which means that they are texts full of meaning. They have discourses of their own. The reality is constructed in social networks in social interactions of everyday life (Berger & Luckman, 1966). In this

study design, it signified a relationship between a photographer and a reader. In the framework of social constructionism, a researcher can interpret these stories and discourses, and construct of reality behind a frame.

For the nonverbal communication analysis of pictures of cases in every case-based context, one nonverbal communication research method was adopted. It was adopted because the author was familiar with this method due to one previous study. The method was based on the action-coding sheet of Burgoon (2005) and Guerrero (2005), which is illustrated in Table 1.

Table 1. Coding sheet of nonverbal behavior (Burgoon, 2005; Guerrero, 2005)

The target		
never look at the partner	1 2 3 4 5 6 7	always look at the partner
exhibited unsteady gaze	1 2 3 4 5 6 7	exhibited steady gaze
gave no eye contact	1 2 3 4 5 6 7	gave constant eye contact
Based on your observation of the target's face, the target		
never smiled	1 2 3 4 5 6 7	always smiled
was facially pleasant	1 2 3 4 5 6 7	was facially unpleasant
smiled a little	1 2 3 4 5 6 7	smiled a lot
conveyed negative affect	1 2 3 4 5 6 7	conveyed positive affect
leaned away from the partner	1 2 3 4 5 6 7	leaned toward to the partner
faced away from the partner	1 2 3 4 5 6 7	faced toward to the partner
sat in a side-by-side position	1 2 3 4 5 6 7	sat in a face-to-face position
leaned back a lot	1 2 3 4 5 6 7	leaned foreword a lot
The distance between bodies was far	1 2 3 4 5 6 7	The distance between bodies was close
The distance between faces was far	1 2 3 4 5 6 7	The distance between faces was close
The target showed		
very little facial expression	1 2 3 4 5 6 7	a lot of facial expression
lots of nervous movement	1 2 3 4 5 6 7	very little nervous movement
frequent rocking or twisting	1 2 3 4 5 6 7	infrequent rocking or twisting
little gesturing	1 2 3 4 5 6 7	a lot of gesturing
little kinesic expression	1 2 3 4 5 6 7	a lot of kinesic expression
a lot of trunk/limb movement	1 2 3 4 5 6 7	very little trunk/limb movement
Based on his/her nonverbal behavior, the target seemed		
anxious	1 2 3 4 5 6 7	calm
inattentive	1 2 3 4 5 6 7	attentive
distracted	1 2 3 4 5 6 7	focused
unalert	1 2 3 4 5 6 7	alert
restless	1 2 3 4 5 6 7	still
flustered	1 2 3 4 5 6 7	composed
bored	1 2 3 4 5 6 7	interested
detached	1 2 3 4 5 6 7	involved
Overall, the target's body position was		
tense	1 2 3 4 5 6 7	relaxed
closed	1 2 3 4 5 6 7	open
rigid	1 2 3 4 5 6 7	loose

Contrast to the original coding sheet and because of the nature of research material, the evaluation of target's voice and speech were neglected and the characterization of conversation was excluded. Action was evaluated by coding sheet numbers (1-7) in such a way that neutral action was coded by numbers 3-5. If, for example, participant always looked at the partner, it was coded by number 7, but if he or she looked at the partner sometimes, it was coded by numbers which were closer to the other end of the scale. By the list of these

nonverbal actions four behavior patterns were reached: 1) physical closeness with the actual distance between people, 2) lean; the degree to which a person's upper trunk is tilted toward or away from the other person, 3) gaze and facing, and 4) body orientation.

Repeatability and reliability of the coding was ensured by double coding technique. During the analyzing process, all pictures were analyzed twice. Both analyses was a responsibility of the author and it was carried out so that there were break of two weeks between coding times. All findings from 30 domains of coding sheet (never look at the partner - always look at the partner, exhibited unsteady gaze - exhibited steady gaze, etc.) were compared in the framework of agreement or disagreement and the percentages of agreement in different coding times were calculated. Thus, repeatability between different coding times can be compared and reliability of the one-coder analysis can be seriously evaluated.

FINDINGS

Over the three border control situations, the authorities had focused on their role and task rather than a media representative who had illustrated them. They had really involved in the inspection and leaned toward to their target (a dog), except when the target was not in the picture. They stood close together when the target was missing and when they compared their notes, but then they looked at each others' papers, not each others' eyes. When the target was in the picture, the distance between authorities was greater and the authorities gave no eye contact with each other. In general, they never smiled and had a little kinesic expression or trunk or limb movement. The authorities appeared calm, attentive and interested. Facially they had neutral expression.

Differences between the contexts were seen when the number of participants increased. There were no smile between two or three persons, but not between four persons either. On the other hand, the participants seemed a little tense and rigid when they all (four persons) stood side by side and had a steady gaze towards the papers that one of them introduced. They stood in a face-to-face position. The situation looked like that only one of the persons spoke and the others listened. They were not anxious, but calm. However, they had focused on their future role and some of them were alert a little.

The authorities had focused on their task during the emergency exercise. In selected picture, two persons were involved and suitably equipped. These persons stood on both sides of a pig, not side by side and they gave no eye contact between each other. Instead, main actor of them looked towards a camera rather than a partner or an animal, which was interpreted as a little lack of interest and concentration on the task. None of the participants had trunk or limb movement towards each other, but the main actor showed limb movements towards an animal. The face and gaze of another person were missing, but the face of the main actor was seen. Based on the observation of this person's face, the person never smiled, was facially unpleasant and conveyed negative affect on the situation.

The person (main actor) showed facial expression only a little and had no nervous movements, but he expressed some signs of anxious and tense attitude on his face. He was inattentive rather than attentive towards the pig, although he tried to concentrate on his role as a person, who had a responsibility of ongoing and unfinished operation. The role of the other

person was the role of an assistant (keep the pig's trunk without movements) and he or she stood in a neutral position close to the pig and the main actor. He or she stood straight, with no lean backward or foreword and without rocking and twisting.

From the perspective of reliability, agreement between two different coding times in border control pictures varied from 73% to 80% according to the picture. Meanwhile, among authorities, repeated references of same nonverbal features in different border control pictures were realized. All pictures were parts of the larger picture of nonverbal behavior of the authorities in Finnish border control context. In this working context, placing the pictures side by side, it seemed that authorities, who stood side by side and listened to each other in one picture, could be calm and focused on the task in the second picture. On the other hand, when the authorities were attentive, involved and interested in their task in one picture, they could also be attentive and focused in the following picture in which common discussion between authorities was established. When the time passed, continuum between the pictures developed and the story about interaction between authorities was completed. The pictures had intertextual relationship with their reflection of deep concentration of greater goal, which was outside the pictures.

The agreement range from 70% to 80% was revealed when all four pictures were involved. In particular, differences in the evaluation of alert or unalert behavior was found in three pictures from border control situations. Moreover, the direction and the firmness of a gaze was difficult to determine in the same uniform way across all the pictures. Nevertheless, authorities in all pictures worked under visible and invisible expectations of responsibility. They had to work under the discourse of responsibility with tight focus on the task, not other people. This was actually seen by the lack of eye contact, by neutral or even unpleasant facially expressions and by little rigid and tense standing positions. The authorities took their duties and responsibilities seriously without smile and closer relationships. This was close to second discourse, which was constructed, discourse of control. The authorities were calm and showed no nervous movements, and thus, gave a message with full control of situation. Because in some situations, however, they behaved oppositely a little, the third discourse, the discourse of fear should not have been ignored. This fear came from the background context, the professional knowledge of animal diseases (rabies and echinococcosis) and their consequences for human life.

CONCLUSION

Through the analysis of all pictures, these authorities took their role seriously. They had shared roles in emergency exercise and in border control situations. They knew the important role of the exercise and border controls and thus, were focused on the task. They were, however, veterinary authorities, who should know their role in these situations. In contrast to previous reports (Amarasekara, 2007; Koskinen, 2012), they comply with same laws and orders. It is not said that the agreement between authorities would have been the same if authorities from different organizations (police, rescue teams, etc.) involved. Each organization has its own culture and own perspectives in its own context. Thus, the description of nonverbal communication between authorities should be cautiously extrapolated to other situations with other authorities or multi-organizational situations.

The analysis revealed a continuum between the pictures when they were placed side by side despite the fact that there were different authorities in different pictures. The pictures could look like a continuum because they had a common background, which provides an important relationship between pictures. This relationship rises from common animal disease context and for example, upon this context the discourse of fear was constructed. Authorities in this study worked in same animal disease context and in further analysis, this context should be deeply involved. In case study designs, in general, also a meaning of context is respected (Baxter & Jack, 2008; Fritzgerald & Dopson, 2009). Conditions outside the pictures can mean strategic goals with fight against animal diseases and in the future, the pictures can be analyzed towards these goals.

Qualitative case study becomes a valuable method for health science research to develop theory, evaluate programs, develop interventions and study complex phenomena within their contexts (Baxter & Jack, 2008). This study gave a preliminary theory framework from veterinary perspective and provided an opportunity for an evaluation of the coding sheet of nonverbal behavior. Because of special nonverbal style (matter of fact, concentrated attitude and face with straight state) in public and civic settings in Finland emphasized by Wilkins (2005), and special nonverbal features of communication focused by coding sheet (smiling, rocking or twisting, kinesic expression) not typical for Finnish authoritative agents, some cultural differences between the sheet and the target were found. It is a question of the validity of this coding sheet. Based on the previous nonverbal analysis among university students and their teachers (Koskinen, 2011), more positive and diverse nonverbal communication would have been expected. Around cases of communication between authorities, one context was represented and this context was not overlapped with educational context. On the other hand, analysis of nonverbal communication of authorities in emergency exercise and in border control situations reflected the previous description of Finnish nonverbal style in public and civic settings in general, and thus, increases the reliability of current findings.

In this study, well-known risk of qualitative research design, subjectivity, could not be totally avoided. Based on these relative low percentages of different coding times there is no guarantee of good repeatability among different coders. On the other hand, facial expressions and some gestures are universal and globally understood. They are texts with full of meaning and they can explored by general categorized standards. Nonverbal behavior is dynamic and context-specific body information with high communicative potential (Burgoon et al., 2000; Guerrero & Floyd, 2006) all over the world. Its (symbolic) meaning among organization researchers is underestimated. The efficiency of information flow, for example, may be improved by paying attention to the ways through which this information is shared. In some situations, nonverbal communication is useful. Then it would be interesting to know when nonverbal communication can enhance co-operation and collaboration between authorities. Accordingly, it would be essential to know, when it will prevent co-operation intentions.

ABSTRACT

Palliative care and end-of-life management is rarely integrated into the public health system in developing countries. 22 years after the genocide, Rwanda has rebuilt its society, including the health sector, devastated during this dark history. In April 2011, the Rwanda Ministry of Health launched its National Palliative Care Policy committing the country to providing high-quality, affordable palliative care services for all people with incurable illness by 2020.

Rwanda became the first country in Africa to adopt a stand-alone policy, strategic plan, and implementation process. Kibagabaga District Hospital began palliative care services for children and adults in 2009 and 2010, respectively. The district integrated the

program across the continuum of care, from the hospital to the community, and set up a Rwandan model of palliative care.

Keywords: Kibagabaga Hospital, Rwanda genocide, palliative care in Africa, public health, morphine

INTRODUCTION

In Rwanda, with 3% HIV prevalence in the general population, 200,000 persons were estimated to live with HIV in 2010 [1]. According to the Treat the Pain, an international program of the American Cancer Society, of the 10,681 Rwandans who died of HIV/AIDS or cancer between 2012-2013, 7,195 (67%) died with moderate or severe pain; reasons included a lack of education/training in palliative care and pain management, limited opioid availability, and burdensome regulation that restricted opioid access [2]. It is clear why palliative care services are necessary. Current palliative care availability in Sub-Saharan Africa is limited and the quality is uneven [3, 4].

This chapter will share the experience at Kibagabaga Hospital, a Rwanda District Hospital, in pioneering palliative care services, as well as the complexity of providing palliative care in a post-genocide society.

PALLIATIVE CARE IN RWANDA

Rwanda is a small landlocked country in Central East Africa with a population of almost twelve million. With a beautiful green landscape, called “the country of a thousand hills” (*Pays des Mille Collines*), it is bordered by the Democratic Republic of Congo to the West, Uganda to the North, Tanzania to the East, and Burundi to the South. Rwanda rose from the ashes of the 1994 genocide to articulate a program of equity-oriented national policies. The launch of *Vision 2020*, a national development plan, set an ambitious health agenda. This was especially resonant as the genocide had “robbed [the nation] of a generation of trained teachers, doctors, public servants, and private entrepreneurs” [5] and had destroyed the health infrastructure. The genocide legacy also included crippling disabilities, war crime rape-transmitted HIV infection, chronic illnesses, and a high prevalence of post-traumatic stress disorder [6].

The Rwandan constitution of 2003 codified health as a right and charged the State with its promotion and implementation [7]. Rebuilding the public health sector centered on strengthening primary care and expanding health services with a variety of development partners, emphasizing access and accountability [8]. A community-based health insurance, *Mutuelle de Santé*, was scaled up nationally in 2005. With a high burden of HIV/AIDS, there was great need for diagnosis and antiretroviral treatment as well palliative care, which was characterized as an “urgent public health problem” [9]. In 2004, the Minister of Health sent a team to Uganda, the first African country to make palliative care a priority [10], to study its palliative care program.

In 2005 the Rwanda Ministry of Health presented a three-day workshop in palliative care in collaboration with partners: the Society of Women Against AIDS, Help the Hospices UK, the African Palliative Care Association, the Rwanda Palliative Care Association, the United States President's Emergency Plan for AIDS Relief (PEPFAR), Partners in Health, IntraHealth International, and Mildmay International. In 2008 the Rwandan Ministry of Health, with IntraHealth and Mildmay, introduced the first "train the trainers" curriculum in four district hospitals (Kibagabaga, Byumba, Rutongo and Nyagatare) to incorporate palliative care principles into the treatment of patients with HIV/AIDS and cancer. Evaluation of this pilot project demonstrated that Kibagabaga Hospital had successfully integrated palliative care as an administrative and clinical priority, opening a palliative care ward for children in 2009 and for adults in 2010. It was thus chosen as a model for duplication in other district hospitals.

In January, 2011, the Rwanda Ministry of Health officially launched its National Palliative Care Policy, committing the country to the provision of high-quality, affordable palliative care services to all people living with incurable illness by 2020 [11]. In 2012, a new Rwanda narcotic control law was enacted, allowing morphine and other opioids to be prescribed as indicated for pain management across all health facilities and in home-based care [12].

Implementation steps continued in collaboration with a number of development and educational partners:

- 2011: The medical director of Kibagabaga Hospital was sponsored to attend the Harvard Medical School Palliative Care Education and Practice program and advise on the implementation of palliative care on a national level
- 2012: The United Kingdom Department for International Development began a three-year project through the Tropical Health Education Trust's (THET) Health Partnerships Multi-country Partnership Scheme to support palliative care integration into national health systems in four African countries (Kenya, Rwanda, Uganda and Zambia)
- An additional physician and two nurses from Kibagabaga Hospital were sponsored to attend a diploma course in palliative care at Hospice Uganda
- The Rwanda Ministry of Health sponsored a national ten-day "train the trainers" palliative care course for multidisciplinary teams (physician, nurse, social worker, psychologist) from all district, teaching, and referral hospitals
- The Butaro Cancer Center of Excellence opened in the Burera district of Northern Province, the first such facility in rural East Africa. Key partners, brought together by the Clinton Global Initiative, included the Rwanda Ministry of Health, Partners in Health, Dana-Farber Cancer Institute, Brigham and Women's Hospital, Boston Children's Hospital, and the Jeff Gordon Children's Foundation
- 2014: The Kibagabaga Hospital medical director, in an exchange experience between low/middle income and high income countries, was sponsored during educational leave as a visiting fellow at St. Christopher's Hospice in London and Mary Stevens Hospice in Birmingham, England. This afforded the opportunity to observe best practices in established systems (procedures, protocols, guidelines), learn from

visiting international colleagues (public policy, advocacy, challenges), and join in a reciprocal exchange of culture and experience

- 2014-2015: The Kibagabaga Hospital medical director, on educational leave, and the director of the pharmaceutical supply chain of the Rwanda Biomedical Center (the implementation arm of the Ministry of Health) participated in the African Pain Policy Fellowship of the Pain Policy Study Group at University of Wisconsin. They reviewed Rwanda's regulation of opioids and made recommendations to the Ministry of Health and Rwanda Biomedical Center to increase availability and accessibility of morphine at the national level. This fellowship also gave experience in framing pain management as a public health issue. As a result, the Ministry of Health increased the availability and formulations of morphine, including developing a national production facility to reconstitute morphine powder into 5mg/5ml solution.

POST-GENOCIDE CONSIDERATIONS

Despite remarkable steps toward recovery, Rwanda remains deeply affected by the 1994 genocide which took the lives of more than one million people in one hundred days and created millions of refugees. Providing palliative care in a post-genocide society requires a strong commitment to humanity in addition to clinical knowledge and skills. The context of this dark and complex humanitarian crisis is complicated to define. It has been important to consider the impact of genocide on both patients and health care providers to develop an approach that will benefit all parties. We regularly learn more from our patients and their families than we teach them, and we must care for them beyond treatments, procedures, and protocols.

The Rwandan culture values stoicism; the expression of feelings and emotions may be seen as weakness. Pain may be seen as an important sign of vitality, of manliness in particular. In addition, physical pain may be deemed trivial or banal compared to the genocide losses suffered by the patient and family. The Kibagabaga Hospital wards are filled with survivors' stories which minimize present pain in comparison to the genocide. Conversely, for some persons a new illness or pain may resurrect genocide loss and amplify suffering.

The Kibagabaga Hospital palliative care team learned that there is an important difference between genocide survivors with a life-limiting illness compared with patients who did not go through that traumatic crisis. We have observed that the survivor always sees the genocide experience as a contributing factor to the current illness. The treatment team must understand that dealing with that history matters as much or sometimes more than standard medical treatment. The psychological context of illness is complicated by survivorship, as the genocide experience adds to the existential distress of a serious or terminal diagnosis. A patient will ask, "Why did I survive the genocide to die from cancer?"

The annual genocide commemoration period provides an example of the complexity of providing palliative care to genocide survivors. Every year, from April to June, the people of Rwanda, from villagers to top officials, commemorate the genocide. This is a period to remember and honor loved ones, to promote unity and reconciliation, to educate to prevent genocide ideology, and to celebrate Rwandan resilience and courage in rebuilding the country since 1994. For most of the population it is still difficult to cope.

Our team has observed that a patient's previously managed pain may become uncontrolled during commemoration. An increase in medication would often be ineffective and could risk dangerous sedation. It has been imperative to develop a strong counseling program to anticipate and address this surge in "total pain," the foundational concept articulated by Cicely Saunders, because of the psychological, social, and spiritual suffering evoked by the commemoration experience.

CASE STUDY OF INTEGRATION OF PALLIATIVE CARE AT KIBAGABAGA HOSPITAL

Introduction

Rwanda is divided into five provinces, which are divided into districts. Districts are responsible for coordinating public service delivery. There are five national referral hospitals, 48 district hospitals, and roughly 440 health centers [14].

In each of Rwanda's 14,837 villages, community health workers are elected by their neighbors and trained and equipped by the Ministry of Health to deliver care and link patients to the health care system [8].

Kibagabaga Hospital is a district hospital located in Gasabo, the largest of the three districts of Kigali City, the capital of Rwanda, with 60% of the 1.2 million population. In 2008 Kibagabaga was one of four district hospitals to integrate palliative care principles into the care of patients with HIV/AIDS and cancer, with training supported by the Ministry of Health, IntraHealth International and Mildmay. Adding a palliative care approach aimed to reduce the psychosocial burdens of patients and families during antiretroviral and chemotherapy treatment.

In 2009, Kibagabaga Hospital, supported by Intrahealth/Mildmay, opened the first pediatric palliative care center for children, and in 2010 palliative care was integrated for adult patients. Each program had separate funding sources. At that time, most district hospitals struggled to cope with the needs of patients who had been transferred from the teaching hospital level to district hospitals. Many patients refused to be discharged home because of a lack of services at the health center and community level. Thus some patients spent months or even years in the hospital. In a Kibagabaga Hospital survey, 95% of patients/families cited "pain" and "lack of information" at the community level as the reason they refused discharge.

Challenges

When international development partners concluded funding for palliative care implementation in 2010, the Kibagabaga administration continued to develop the program in the hospital, but with minimal financial support compared to funding for tuberculosis, malaria, and HIV/AIDS treatment.

Our multidisciplinary team committed to three central concepts for our palliative care program:

- Holistic care: give attention to effective pain management, including making morphine available to treat physical pain. Assess “total pain,” addressing psychological, social, and spiritual aspects – a new concept for our setting – as part of daily management of patients and their families.
- Financial discipline: reduce cost by extending palliative care service to the community, eliminating the need for patients to travel to the hospital for prescriptions. Create home-based care services and a community volunteer program.
- Cultural value: learn from our patients; honor patient and family dignity; contribute to restoring the humanity lost during the genocide by incorporating “*Ubuntu*” philosophy, an African concept of interdependence detailed below.

It was also important to identify challenges within the system, such as

- Inadequate pain management knowledge and skill.
- Restricted opioid availability and use: by hospital protocol, morphine was used only for cesarean section postoperative care, was limited to a single 3 or 4 mg dose, and could be ordered only by an anesthesiologist. Prescribing a dose of morphine required multiple signatures (the prescriber, the pharmacy, the anesthesia department, and sometimes the medical director of the hospital) in red ink.
- Limited inpatient capacity: the hospital bed occupancy rate was 120% and average length of stay was six days. Patients with chronic illness were referred from teaching hospitals to the district hospital, where they subsequently refused discharge.
- Lack of outpatient care: there were few discharge resources and communication between the hospital and the community was poor.

Palliative Care through “Ubuntu Philosophy”

Education in palliative care was a cornerstone of change at Kibagabaga Hospital, with internal training of doctors, nurses, social workers, psychologists, and physiotherapists. To sustain our mission in the face of challenges, it was essential to ground our new knowledge and skills in African culture rather than duplicate a Western model. We found inspiration in the *Ubuntu* philosophy expressed in Xhosa, one of South Africa’s eleven official languages, as “*Umntu ngumntu ngabanye abantu*,” “I am what I am because of you” or “a person is a person through other people.”

We recognized that a patient must be understood as a member of society, not as a disease or data point. *Ubuntu* is the “*raison d’être*” of the African context, going beyond an individualistic perspective based on self-interest to a mutual participation grounded in interdependence and humility. It is about “we” not “me.” Through the *Ubuntu* ideal, we embraced our African communal responsibility to support patients and their families with humane dignity.

Another expression of *Ubuntu* says: “Your pain is my pain, my wealth is your wealth, your salvation is my salvation”.

Connecting the clinical concepts of palliative care to this traditional African philosophy supported the program’s acceptance and integration. It also framed our commitment to

palliative care as transforming not just the hospital but our country, restoring the sense of humanity lost during the genocide.

Palliative Care beyond the Hospital Ward

A survey of patients and families revealed that they experienced anxiety, frustration, and stress when they visited the hospital for palliative care consultation. Many claimed this distress was worse than the disease itself. The main cause was difficulty finding our location on the hospital campus, which came from a lack of knowledge about our program among the non-clinical staff. Thus, we organized a three-day “sensitization” workshop that included housekeepers, drivers, cashiers, transporters, gardeners, and security guards, as well as human resources, public relations, and data management personnel. As a result, all hospital employees learned about palliative care, gained a better understanding of the burdens of patients and families, and participated in creating a helpful visitor experience. This resulted in reduced patient/family stress and increased satisfaction for all parties.

In clinical management, the hospital revised its opioid protocol so that morphine could be ordered for moderate to severe pain via a simple prescription by a physician trained in pain management. Morphine use, ordered in only 4% of patients in 2010, increased to 25% of patients in 2012.

To extend our program, we set up a palliative care district network (PCDN) from the hospital to the community. We trained two nurses from each health center in our catchment area in pain assessment, management, triage and supportive care. We also created a curriculum for community health workers to be our eyes and ears in the community, training 481 (one per village) in a one-month period. They were educated to identify the most common symptoms in palliative care (pain, dyspnea, nausea, vomiting, constipation) and report to the health center nurses. The PCDN helped to reduce the flow of patients from the community to the hospital, decreased the burdens of transportation and living at the hospital for family caregivers, transferred competencies to the health center and community level, and involved the community in caring for its members. The Ministry of Health is evaluating the PCDN concept for replication at a national scale.

CONCLUSION

In 2014, the first ever-global resolution on palliative care, World Health Assembly 67.19, called upon the World Health Organization (WHO) member states to improve access to palliative care as a core component of health systems, especially in primary and community-based care [14].

In the past 22 years Rwanda has made remarkable steps towards recovery. The country has rebuilt the national sense of security and stability and invigorated the economy, including the health sector. However, there are still many issues which threaten the development of countries like Rwanda, such as inadequate health infrastructure, lack of access to education, high population growth, a large number of orphans, and the increasing burden of non-communicable diseases.

Even as ambitious plans are implemented, resources remain limited. Patients often have advanced disease at the time of diagnosis, limiting curative options. But care can be given, suffering can be addressed, and all patients with serious illness can benefit from incorporating palliative care into treatment.

The experience of Kibagabaga Hospital demonstrates that it is feasible for hospitals in low and middle-income countries to develop and integrate palliative care services for the benefits of patients, families, and health care providers with a minimal budget. Kibagabaga Hospital has become a center of excellence for palliative care services in Rwanda and as well as an exemplary setting for health care providers and health professions students to learn this comprehensive approach.

BIOGRAPHICAL SKETCH

Christian R. Ntirimira, MD

Medical Officer, Department of Advocacy & Research (RPCHO)
Palliative Care Educator from Harvard Medical School
Trainer of trainers in Palliative care & Cancer Training at National Level
African Pain Policy consultant
African Cancer Leaders Institute Fellow (AORTIC)
Advocate in Palliative Care & Cancer education

E-mail: ntiheritier@yahoo.fr, ntiheritier@gmail.com

Dr. Christian Ntirimira is the Head of Advocacy & Research department of Rwanda Palliative Care & Hospice Organisation (RPCHO) and former Director of Kibagabaga District Hospital in Kigali (2010-2013). A Palliative Care Expert and Educator, Dr. Ntirimira pioneered integration of end of life care into health services rendered to Rwandan patients with chronic illnesses in acute care and community settings.

Through his program, more than 1500 health care providers and community health workers have learned the principles of cancer & palliative care leading to a five-fold increase in prescription of morphine, an essential pain medication. Dr. Ntirimira has published on the subjects of palliative care and health systems in notable academic journals, including the

Lancet, the online palliative care resource for health professionals, www.ehospice.com, and in Rwanda's top English daily newspaper, The New Times. Dr. Ntizimira serves on the Rwandan Ministry of Health Non-Communicable Diseases Synergies Group and the National Palliative Care Policy Group. He was a 2013-2015 Palliative Medicine Fellow at the McConnell Heart Health Center Homereach Hospice in Columbus, Ohio, and 2014-2015 African Pain Policy Fellow at the University of Wisconsin-Madison Pain & Policy Studies Group/World Health Organization Collaborating Center on Pain Policy in Palliative Care. Dr. Ntizimira is a Researcher collaborator at Harvard Global Equity Initiative - Lancet Commission on Global Access to Pain Control and Palliative Care (GAPPCP). He is a 2015-2017 African Cancer Leaders Institute Fellow and member of the African Organisation for Research & Training in Cancer (AORTIC). Dr. Ntizimira holds a Doctor of Medicine degree from the National University of Rwanda and received his palliative medicine training at Harvard Medical School.

Chapter 519

RECOGNITION OF INFORMAL LEARNING IN VIRTUAL COMMUNITIES OF PRACTICE: A CASE STUDY OF PUBLIC HEALTH WORKERS

***Miren Fernández-de-Álava, PhD^{1,*}, Daniel Giménez², Txus Tolosa²,
Antoni Colomer², Pilar García² and Jordi Vendrell²***

¹School of Education, Universidad de las Islas Baleares, Mallorca, Spain

²Public Health Agency of Catalonia, Catalonia, Spain

ABSTRACT

Having identified the lack of a theoretical substrate and research on praxis in informal learning in the Spanish—specifically Catalanian—context as her core research problem, this chapter focuses its attention on a research study conducted in 2012-2014 in order to, among other objectives, propose a system for certifying informal learning in the field of Public Administration.

Five virtual communities of practice (vCoP) from the Public Health Agency of Catalonia were studied. Research was conducted by means of a self-applied online questionnaire with three dimensions represented by seven factors and 61 items, 30 in-depth interviews with 17 questions, and document analysis. Quantitative data was analyzed using SPSS v17 Inc. performing descriptive and inferential tests, whereas qualitative data was analyzed using MAXQDA 11.

Results indicate that is the moment to make progresses in vCoP by establishing a system that certifies informal learning acquired after participating in vCoP. Although it is difficult in delimitation, Public Health workers established a series of criteria essential for evaluating participation: (a) improvement made in workplace; (b) transfer of the learning process and knowledge/skills gained to the workplace; (c) integration of final products into the workplace; and (d) assessment of the quality and quantity of hours invested outside the workday. In this sense, we highlight the discussion concerning the development (or not) of methodologies that measure learning done. We can confirm that it is still necessary to make progress in the establishment of evaluation procedures that have the same validity and reliability of those used in formal systems.

Keywords: virtual community of practice, informal learning, workplace learning

INTRODUCTION

We live in a time where challenges are different from those in past years, and consequently the answers to those problems are evolving—a fact that highlights the necessity of constant adaptation that can only be carried out through learning—formal, informal, and training.

Considering context and adaptation as elements that differentiate one organization from another—organizations are immersed in finding models and strategies that allow their members to share their knowledge and work collaboratively, in order to get effective results at the individual, group, and organizational level. In fact, individual and organizational developments are closely related. As Siemens (2014) pointed out, organizations and persons are learning organisms. Individual learning does not guarantee organizational learning, but it would seem impossible that organizational learning occurs without individuals learning (Argyris, 2001; García del Junco & Dutschke, 2007; Senge, 1992). In fact, an important percentage of the individual learning required for organizational learning is developed through mechanisms of informal learning in the workplace (Cross, 2007; Fernández-de-Álava, 2014; Marsick & Watkins, 1990).

In the recent years the number of studies concerning informal learning and communities of practice (CoP) are increasing (Bate & Robert, 2002; Dixon, Allen, Burgess, Kilner, & Schweitzer, 2005; Gairín et al., 2011); nevertheless, there are very few such studies in the field of Public Administration. Furthermore, there is even little recognition of, and information about the informal learning that is generated as a consequence of this collaborative work. So, having identified the lack of a theoretical substrate and research on praxis in informal learning in the Spanish (specifically Catalanian) context as the core research problem, this chapter focuses its attention on a research study conducted in 2012-2014 in order to, among other objectives, establish a series of considerations for evaluating participation in virtual communities of practice (vCoP), and informal learning acquired through this participation.

BACKGROUND

Informal Learning in Virtual Communities of Practice

Many scholars have tried to understand and explain informal learning (i.e., Boud & Middleton, 2003; Eraut 2004; Fernández-de-Álava, 2014; Livingstone, 1999; Marsick, 2009; Schugurensky, 2000; Straka, 2004). In 1990, Marsick and Watkins defined informal in contrast to formal learning by affirming that “[...] it is not typically classroom-based or highly structured, and control of learning rests primarily in the hands of the learner [...]” (Marsick and Watkins, 1990, 12); but other authors (e.g., Billett, 2002, 8) avoid this dichotomy pointing out that “it is probably neither helpful nor precise to describe learning outcomes solely on the basis of the structuring of learning experiences.” Even though we

cannot leave out some differences between formal and informal learning, such as design, focus or certification, we agree with Billett (2002) that both learning are two ends of a continuum with considerable overlap.

For Billett (2002), the description of workplaces as informal learning environments is unhelpful due to the use of terms such “informal” or “unstructured” probably because “informal learning can be deliberately encouraged by an organization or it can take place despite an environment not highly conducive to learning” (Marsick & Watkins, 1990, 12). So, the definition of “informal learning” used in this chapter is the one whereby informal learning is acquired through professional practice and that is propelled by challenges that appear in daily activities. Although it is not necessarily a collaborative learning experience, collaboration can be encouraged, deliberately, by the organization (Fernández-de-Álava, 2014; Marsick & Watkins, 1990; Marsick, Fernández-de-Álava, & Watkins, 2015).

Among those mechanisms of informal learning are communities of practice (CoP); a term coined by Lave & Wenger (1991). In CoP the organizational area is nothing other than a means of giving form to the different communities to which we belong in our day to day lives: family, friends, hobbies, etc. (Wenger, 1998). Through the establishment of a network structure (Castells, 1997), dialogue lends meaning to the learning, given that knowledge is constructed through feedback. However, and frequently, it is hard to define the boundaries between this type of network, CoP, and other structures in organizations, such as formal working groups, interest groups or project teams (see Table 1).

Table 1. Kinds of structures similar to CoP

Form of organisation	Purpose	Affiliation	Cohesion	Length
CoP	To develop its members' capacities. To build and exchange knowledge	Self-selection	Passion, commitment, and identification with the group's expert knowledge	Until the interest in maintaining the CoP disappears
Formal network	To perform specific jobs within a given domain of knowledge	Formal assignment (by a senior manager)	Workplace requirements and shared objectives	Until the next reorganisation or until the job is finished
Formal working group	To provide a product or service	Formal affiliation	Workplace requirements, and shared objectives	Until the next reorganisation
Informal network	To exchange knowledge within a given domain of knowledge	Voluntary involvement (colleagues, friends, acquaintance, etc.)	Mutual needs, and individual interest	Until the members lose interest in being connected
Interest group	To share knowledge, learn, and to create knowledge	Voluntary, and open involvement	Commitment to and identification with the target of interest	Until the interest disappears
Project team or target community	To perform specific jobs	Formal assignment (by a senior manager)	Project milestones, and objectives	Until the project is completed

Source: (Al-Hawamdeh, 2003; Collison & Parcell, 2003; Hislop, 2005; Müller-Prothmann, 2006; Wenger & Snyder, 2000).

Fernández-de-Álava (2014) studied CoP, but with an intensive use of technology: virtual communities of practice (vCoP). According to Kimble & Hildreth (2005) and Wenger (1998), apart from facilitating informal learning, vCoP encourage knowledge creation and management (KCM) and personal and professional development. In this respect, information and communication technologies (ICT) have come to play a fundamental role in the embedding of new forms of learning and collaborative cultures (Cobo & Moraver, 2011). So, the form used in this chapter of “vCoP” are those groups of people who share a common interest, problem or professional challenge; share their knowledge, skills and experiences (Lave & Wenger, 1991; Wenger, 1998); and learn together due to this exchange, but with an intensive use of technology (Fernández-de-Álava, 2014).

Recognition of Informal Learning

Marsick, Fernández-de-Álava, & Watkins (2015) pointed out different ways for recognizing informal learning, such as the Learning Practices Audit (Watkins & Wiswell, 1987), or the Dimensions of the Learning Organization Questionnaire (Watkins & Marsick, 1997). In 1987, Watkins and Wiswell developed a Learning Practices Audit, in order to self-assess the amount of hours per month spent participating in formal, informal or incidental learning activities. Some years later, in 2000, Watkins and Cervero went back to this Learning Practices Audit and modified it, when asked to assess informal learning for expert testimony about learning practices in the accounting context. Another example is Lohman (2006, 2009) who assessed the availability of resources that support informal learning, or Skule (2004) who studied learning conditions at work for understanding and assessing informal learning in the workplace. According to this framework, factors that made jobs more learning intensive, favoring informal learning, were (Skule 2004, 14): (i) “high degree of exposure to changes,” (ii) “high degree of exposure to demands,” (iii) “managerial responsibilities,” (iv) “extensive professional contacts,” (v) “superior feedback,” (vi) “management support for learning,” and (vii) “rewarding of proficiency.” Finally, we cannot let the Dimensions of the Learning Organization Questionnaire (DLOQ) (Marsick, 2013; Marsick & Watkins, 2003; Watkins, & Marsick, 1997) pass. This questionnaire was designed to assess organizational learning culture. Specifically, it measures how organization’s climate, culture, systems, and structures impact on workers learning “To support such learning, one needs to build a learning climate and culture. Climate and culture built by leaders and other key people who learn from their experience, influence the learning of others, and create an environment of expectations that shapes and supports desired results that in turn get measured and rewarded” (Marsick & Watkins, 2003, 134). So, when learning culture is strong, it nurtures [informal] workplace learning.

THE ORIGIN OF vCoP IN THE PUBLIC ADMINISTRATION OF CATALONIA

In 2004, the Directorate General for Citizen Attention (DGAC, is the Spanish/Catalan acronym) embarked upon a process of change in order to abandon its traditional structure—

deemed too hierarchical and rigid for optimal learning—for one more substantially more horizontal that would be based on knowledge sharing through vCoP. In order to achieve this goal, the DGAC established an online collaborative working environment, e-Catalunya (<http://ecatalunya.gencat.cat>), for all the staff of the Catalan Public Administration. The DGAC vCoP model is characterized by the following (Barrera-Corominas, Fernández de Álava & Gairín, 2014):

- **An intensive use of technologies.** e-Catalunya is the main communication channel because it is the online institutional platform. Nevertheless, there are two in-person meetings: one at the beginning of the vCoP and another one at the end. The first of these is useful for participants to get to know each other, to select the moderator, to define objectives and to schedule the latter at a time permitting development of an end product. This end product is distributed to participants in the vCoP, to participants from the other vCoP's, as well as to other internal or external professionals.
- **Participants.** Participants are, of course the core of any vCoP. Of these, there are usually three types: (i) active, those who participate consistently, promoting an enriching dialogue through the exchange of information; (ii) sporadic, those who read contributions and, from time to time, write in their own experiences, opinions, etc.; and (iii) passive or lurker, those who are in the periphery, that is, not participating in the active dialogue but reading the contributions (Rodríguez-Gómez, 2011).
- **Moderator.** He/she is the person who drives the vCoP dynamic, and he/she is responsible for guiding the process in order to achieve the objectives defined in the first face-to-face meeting and to produce an end product. The Moderator has to create a pleasant climate; to motivate participants and to encourage their taking part, to structure their work and finally, to close the debate with some consensus (Sanz, 2012).
- **A debate.** Developed through tools such as the forum or the wiki, and complemented by photos, documents and bibliography/references.
- **An end product.** Every vCoP must produce some kind of material (manual, three-page leaflet, programme, protocol, etc.) that is useful on three levels: individual, group and organizational. Once validated by the Executive Board (see Figure 1), this end product is the innovation the vCoP diffuses to others.
- **A certificate.** Participants and moderators of those vCoP that create an end product, receive a certificate of these 40 hours of training that are required. Due to the different roles of vCoP, participants' diploma certificates the training received and moderators' diploma certificates the training delivered.

It is important to point out that, by collective agreement, the staff of the Catalan Public Administration have to do 40 hours of training within their work schedule. To fulfil this obligation, they go to formal training activities (classroom and online) that the Public Administration designs and offers to them. At the end of the course(s), the course deliverer awards a diploma to the staff who have attended all the hours, which enables them to apply for promotion when the competitive exams/ civil service examination are announced.

Source: Internal documents of the Public Health Agency of Catalonia.

Figure 1. Procedure to recognise vCoP's end products.

However, at the same time, there is a second and informal way to be trained: the abovementioned participation in a vCoP - although with this approach there are no specified numbers of hours. Nevertheless, for the competitive exams/civil service examination only diplomas issued by the Public Administration are considered valid.

The Public Health Agency of Catalonia (ASPCAT, by Its Spanish/Catalan Acronym)

Law 7/2003, of 15 April, (DOGC number 3879, of 8 May, 2003), represented the beginning of a reform of public health services, based on the organization of the supply of health protection services, through the creation of the ASPCAT. Consisted of multidisciplinary teams formed by health professionals such as biologists, chemists, doctors, veterinarians, and other non-health professionals (caretakers, secretaries...), the ASPCAT is established with the aim of promoting and protecting health, and of preventing and managing epidemiological and food alerts.

Regarding the implementation of vCoP, it organized a journey whose aim was to define its training model based on work teams, informal learning, and vCoP. Basically, the ASPCAT

tried to replace individual work and isolated routines for teamwork and collaborative environments, to provide new employees with necessary skills, to improve basic skills of former employees, to stimulate internal promotion, to promote ways of informal learning and communities of practice and to strengthen transversal training within public health workers.

In 2008, ASPCAT started a pilot project of knowledge creation and management through vCoP in order to prove the interest of health workers in sharing their knowledge among other colleagues. ASPCAT developed 6 vCoP involving 76 staff-members. Their success led to form, a knowledge management team in 2009, and to approve a Plan aimed at creating a knowledge sharing culture. Also to create horizontal networks to encourage informal learning, to encourage professional development and to meet organizational requirements.

ASPCAT repeated the experience year after year and since 2014, it brought together 533 employees who have worked on different topics such as chemical dangers related to sunflower oil: description and preventive measures; water not suitable for human consumption and health education in schools: food hygiene.

METHODOLOGY

This chapter establishes a series of considerations for evaluating participation in vCoP and informal learning acquired through this participation. It draws on quantitative and qualitative data from research conducted in 2012-2014.

Sample

The scope of this study comprises all professionals that participate in vCoP, or moderate vCoP in the ASPCAT. Five successful [i.e., their collaborative work has resulted in a useful end product for the participants of the vCoP, the group and the organization] vCoP were studied. The data-producing sample consists of 33 professionals. It should be pointed out that two of the five successful vCoP were selected intentionally, based on the interviews done within research (Gairín et al., 2011), whose aim was to outline factors for success in vCoP in the two aforementioned Departments:

- Time/temperature binomial in the food industry – This vCoP was born due to the difficulties that inspectors found when they have to do inspections or audits when it comes time to evaluate the parameters of time/temperature. “The topic time/temperature binomial has a lot of controversies. So, all professionals who are in this vCoP is because we are interested in the topic and because we want to give our colleagues some work tools,” said one of the participants. The end product was a useful tool guide to them because participants describe all the necessary steps to evaluate the parameters of time/temperature in order to guarantee food safety.
- Manual on post mortem examination and dictum of fresh meat – All the participants of this vCoP work in slaughterhouses, and in isolated environments (that is, they work alone, at night and they have no interaction with other colleagues). For that reason, the opportunity of working in vCoP attracted them, because it can be a social

network where they can talk with other colleagues and solve challenging problems. An ASPCAT member noted, for example: “Slaughterhouses are isolated areas within the ASPCAT. Veterinarians work alone, in particular hours, in a group that does not interact with the rest of the organization, and they have the necessity to open their mind.” The end product of this vCoP is very useful because it contains a lot of photography and they describe the different lesions and diseases that animals can have and why they are suitable (or not) for consumption. In fact, it has been disseminated outside the Catalan slaughterhouses. This usefulness has been noted by an ASPCAT member: “I think that vCoP from slaughterhouses have been very successful because their end products have being very useful for this group.”

Instruments and Variables

The instruments used were a digital format self-applied questionnaire via LimeSurvey to facilitate response due to the geographic dispersion of the participants in and moderators of the vCoP. The items proposed were of two types: (1) 5-point Likert evaluation scale, from 1 - strongly disagree to 5 - strongly agree, for all items apart from those corresponding to mechanisms of informal learning and (2) multiple choice question for the latter. None of the items was constructed in a negative sense. The variables considered in this chapter are the ones related evaluation and certification of informal learning derived from vCoP.

After the results had been obtained from the questionnaire, interviews were conducted with the vCoPs’ managers, participants and moderators, in order to compare and contrast the same. The questions, which were asked openly, covered all of the items of the survey, apart from those of identification. Additionally, document analysis was the other data collection method.

Data Analysis

Quantitative data was analyzed using SPSS v17 Inc. performing descriptive and inferential tests, whereas qualitative data was analyzed using MAXQDA 11.

RESULTS

The outcomes presented refer only and exclusively to those data of considerations for evaluating participation in vCoP and informal learning acquired through this participation. Table 2 indicates descriptive statistics –the median and standard deviation– of each items included in ‘considerations for evaluating participation in vCoP and informal learning acquired through this participation’. Specifically, median score varies according to agree and neutral (2.80), and disagree and strongly agree (4.20). The median total score of the items and participants is 3.90; serving as a central tendency index in the analysis. Standard deviation varies between 0.79 and 1.30, the global average being 0.97.

Table 2. Descriptive statistics for items included in “considerations for evaluating participation in vCoP and informal learning acquired through this participation.”*** denotes significance**

Considerations for evaluating participation in vCoP and informal learning acquired through this participation	Median	Standard Deviation
Participation in vCoP outside working hours	2.80	1.30
Development of an end product	4.20	0.94
Usefulness of new competences acquired through the participation in vCoP for the professional practice	4.26	0.79
Improvement in professional practice due to the participation in vCoP	4.23	0.87
Transfer of knowledge/skills acquired through the participation in vCoP to other contexts	4.00	0.96

In general, those indices show a closer state of notable agreement. Nevertheless, we should specify that the effect produced by item ‘Participation in vCoP outside working hours’ because its result is quite lower than the other items, lowers the global results. Standard deviations, show moderate scores being 0.97 the global average (24.87% of the median), with the exception of the abovementioned item. From this outcome, we deduce some dispersion in responses.

In order to go into detail about results shown in Table 2, we applied t-test against the global mean. Statistical significant differences were found in four of five items that make up the dimension “considerations for evaluating participation in vCoP and informal learning acquired through this participation” (see Table 3). Specifically, statistically significant differences exist within four issues that could be considered when assessing participation in vCoP and informal learning acquired through this participation: (i) participation in vCoP outside working hours ($p = 0.028$); (ii) development of an end product ($p = 0.011$); (iii) improvement in professional practice due to the participation in vCoP ($p = 0.031$); and (iv) transfer of knowledge/skills acquired through the participation in vCoP to other contexts ($p = 0.018$).

Table 3. T-test results of items included in “considerations for evaluating participation in vCoP and informal learning acquired through this participation”

Considerations for evaluating participation in vCoP and informal learning acquired through this participation	M	St Error	t	p
Participation in vCoP outside working hours	3.18	0.22	-2.23	.028*
Development of an end product	4.52	0.14	-2.61	.011*
Usefulness of new competences acquired through the participation in vCoP for the professional practice	4.33	0.16	-.700	.486
Improvement in professional practice due to the participation in vCoP	4.48	0.15	-2.20	.031*
Transfer of knowledge/skills acquired through the participation in vCoP to other contexts	4.30	0.15	-2.42	.018*

The results derived from the self-applied online questionnaire were, afterwards, extended through interviews and document analysis. So, even though some interviewees were against assessing participation in vCoP because certification could distort vCoP (becoming another training process) “I do not agree with getting compensations. It can be dangerous.” “If you participate in vCoP, you will receive a t-shirt. It is not appropriate for vCoP and learning” or

“with or without recognition, vCoP should run because those who want to participate for training hours they can assist to formal training courses [...] it has no sense,” the vast majority thought that recognition is a way to appreciate the end product, the hours spent, the knowledge/skills acquired, and the value of learning. Likewise, it is a way for legalizing the process. “Managers should find a way to recognize vCoP and informal learning. It is not just a verbal gratitude”; “I spent around 100 hours participating in vCoP [...] it has been years since the ASPCAT offered training courses... so, at the very least the ASPCAT should recognize our work”; and “there should be any way to recognize informal learning. Participation in vCoP enriches participants and moderators, but end product enriches the organization, because those who have not participate also use them and learn.”

Regarding “participation in vCoP outside working hours,” interviewees pointed out that the inclusion of participation in vCoP in the workday represents a reduction of work at home. The majority of participants and moderators participated in vCoP outside working hours that is, in the afternoon and weekends: “I did a lot of work at home. At the slaughterhouse is very difficult to work because we have a huge work volume”; which means that they gave different days a week to participate in vCoP and not to leisure. “According to the e-Catalunya, people participate more during afternoons or weekends, and not during working hours.” So, “the recognition of hours spent will be symbolic because I remember myself uploading documents or calling colleagues during Sundays, and this work done is not recorded, and this is far from being recognized.”

Concerning the “development of an end product,” interviewees pointed out that end products improve professional practice, increase quality of work, and help to personal and professional development. As previously mentioned, at the end of the vCoP participants and moderators should submit an end product as a result of the collaborative work. The end products should improve professional practice but there should be no pressures within the vCoP. As the Plan approved in 2009 states: the delivery of the end product should not have more weight than the learning itself. As a moderator pointed out: “The development of an end product involves different efforts: to motivate, to manage, to set and keep the pace, to format, to homogenize the style (because every participant writes and communicates differently) [...].”

“The main aim of vCoP is that they are useful to public health inspectors.” We have to remember that participants and moderators share knowledge and skills in order to learn and improve their professional practice. “We, as professionals of the ASPCAT, have different backgrounds, knowledge, skills... so let’s share them and create documents that are useful to all professionals because perhaps I am not an expert in milk because I am in vegetable disinfection. So, my end product could make easier your work, and your end product, my work. That is great.” In other words, optimum conditions for vCoP should increase the quality of public services, their effectiveness and organizational outcomes. “The participation in vCoP enriches your background and improves the quality of your work.” Therefore, participants and moderators transfer the knowledge/skills acquired through the participation in vCoP to other contexts.

In short, and in addition to these considerations, interviewees highlighted other considerations such as: (i) the integration of final products into the workplace; (ii) the integration of participation in vCoP into schedule; (iii) the value that ASPCAT places on vCoP and hours spent; and (iv) the role of moderator. “If the ASPCAT integrates participation in vCoP into the schedule, all participants and moderators would make the most

of them. I trust them and I have complete faith in the end products. Their end products are good for my work.”

DISCUSSION AND CONCLUSION

Although there are great progresses in the validation of competences acquired non-formally or through professional experience, we must take into account that the aim of evaluation, in comparison to formal system, is complex having, therefore, bigger difficulties to guarantee its reliability and validity (European Commission, 2012). Nevertheless, as UNESCO (2012) pointed out, we must provide (to all of the population) the opportunity to access and participate in any learning situation and to value its results. For that reason, if ASPCAT, in 2007, thought about the different ways of learning, creating vCoP as a result, now is the moment to make progresses in those programs – establishing a system that certifies informal learning acquired after participating in vCoP.

Despite practically complete lack of European and national tools and instruments for validating and accrediting informal learning, ASPCAT can take as a reference Law 5/2002, of 19 June; Royal Decree 1506/2003, of 28 November; and Royal Decree 1224/2009, of 17 July. This would involve the evaluation of professional competences acquired through vCoP, with reference to the CNCP basis (see Chapter 6, section 6.2.).

If competences previously acquired informally are to be evaluated and recognized, we must carefully consider which knowledge and/or skills must be taken into account— or otherwise omitted them because of their unique contextual nature. Although it is difficult in delimitation, participants and moderators establish a series of criteria essential for evaluating participation in online communities of practice and informal learning acquired through it. The considerations that would be necessary for doing so are: (a) improvement made in workplace; (b) transfer of the learning process and knowledge/skills gained to the workplace; (c) integration of final products into the workplace; and (d) assessment of the quality and quantity of hours invested outside the workday.

It is important (and surprising) to recognize that few participants and moderators think that hours invested outside a workday must be considered in this evaluation of participation in vCoP and in informal learning acquired through this activity. Digging deeper into this issue in the interviews, we discovered that what they consider important is not a matter of counting hours but rather, of integrating final products into the workplace. By doing so, competences acquired can be corroborated and the acquired learning transferred, via publication of the learning of participants and moderators, to the workplace. Thus, through the establishment of a system that certifies informal learning acquired through vCoP in Public Administration, we provide the opportunity to recognize competences. Nevertheless, each person has the right to access (or not) this accreditation.

Chapter 520

MENSTRUATION AND DEPRESSIVE DISORDERS: A RECIPROCAL RELATIONSHIP THAT CALLS FOR PUBLIC HEALTH AND CLINICAL CONCERN

Rachel Levantovsky*

University of Massachusetts, Amherst, Massachusetts, USA

INTRODUCTION

Depression is the most common psychiatric illness experienced by women, and the second greatest cause of medical burden in this population [1]. Before puberty, rates of mental illness, and particularly depression, are highly comparable across all genders. However, by age 15, girls are twice as likely to have experienced Major Depressive Disorder (MDD) than boys [1]. Coincidentally, this is around the time that a girl is likely to have her first menses, as the median age of menarche is 12.43 years in the US, and is estimated to be about 13 years worldwide [2, 3].

The menstrual cycle is intricately linked with many aspects of a menstruator's mental health. Premenstrual Syndrome (PMS) is a diagnosis in women of reproductive age that involves the manifestation of both physical and affective (i.e., emotional) symptoms during the luteal, or premenstrual, phase of the menstrual cycle. The worldwide prevalence of PMS is difficult to estimate, as studies vary considerably in their definitions of PMS and their assessment tools. Studies conducted in the US using criteria established by the American Congress of Obstetricians and Gynecologists estimate that 15-20 percent of menstruators experience clinically significant PMS [4]. The most severe symptoms of PMS tend to appear in a menstruator's late twenties and worsen during the thirties [1]. Importantly, multiple studies have found that women with PMS are more

* Corresponding Author's Email: rachel.levantovsky@gmail.com.

likely to suffer from MDD or develop an affective disorder than those who do not have PMS [5].

Many other factors related to menstruation, apart from PMS, also may have implications for mental health. Early puberty, and early menarche are associated with increased rates of psychopathology [6]. Throughout the menstrual cycle, women tend to experience varying levels of stress during the different phases, both in terms of subjective stress response and in neuroendocrine fluctuations [7]. During the premenstrual phase in particular, women have reported the worsening of symptoms of depression, social anxiety, obsessive compulsive disorder, and psychosis [8]. These patterns of poor mental health are even more pronounced among the most severe cases of psychiatric illness as 37 percent of women who are hospitalized for such illnesses had their last menses within five days of being admitted [9].

These observed associations between menstruation and mental health, particularly with depressive disorders, pose significant health risks for women. Depressive disorders including MDD, dysthymic disorder, and seasonal affective disorder can be exacerbated during the luteal phase of the menstrual cycle [10]. For MDD in particular, the risk of recurrent episodes of this disorder increases with each subsequent episode [1]. Thus, evidence suggests that the menstrual cycle has the capacity to increase the severity of future MDD symptoms and episode length by intensifying a menstruator's current episode. This risk is especially concerning since MDD is responsible for up to 35 percent of all completed suicides [1].

In order to promote the mental health and well-being of menstruators, it is critical that the relationship between menstruation and depression be better understood. Strategies to improve can then be developed to aid in the clinical care of those who menstruate and have a depressive disorder. This chapter discusses these associations and their implications in detail.

MENSTRUATION AND DEPRESSIVE SYMPTOMS: A REVIEW OF THE LITERATURE

Depression Affects Menstrual Symptoms

The association between depression and menstruation is evident in menstruators of all ages. In one cohort of 154 girls of ages 11, 13, 15, and 17, a significant correlation between menstrual and depressive symptoms was established [11]. Two questionnaires were administered to quantify symptom experience and severity - a Menstrual Symptom Questionnaire (MSQ) and the Children's Depression Inventory (CDI). The CDI is a self-reported survey of 27 symptoms of depression that has been demonstrated to have high reliability since its introduction in 1992 [12]. The MSQ grouped symptoms reported by the subjects into five factors of dysmenorrhea. The most-reported symptoms by the cohort, in decreasing order, were menstrual pain, premenstrual pain, premenstrual bloating, premenstrual negative affect, and menstrual back pain [11]. In both surveys,

higher survey scores corresponded to higher symptom severity, and instruments were assessed for internal consistency and reliability.

The results depicted a clear trend of increasing number and severity of menstrual symptoms in girls who had greater depression. Each of the five menstrual factors were significantly and positively correlated with CDI scores. Premenstrual negative affect had the greatest correlation of 0.44 ($p \leq 0.001$) [11]. The correlation between premenstrual pain and symptoms of depression were also highly significant ($p\text{-value} \leq 0.001$), though was slightly weaker in magnitude at 0.34. The three remaining factors were significant ($p \leq 0.01$), and the correlations ranged from 0.27-0.30 [11]. Despite the fact that menstrual pain was the most reported of the symptoms, it did not have the greatest correlation with depressive symptom scores. These results suggest that depression affects premenstrual symptoms more than those experienced after the onset of menses. Additionally, the especially strong positive correlation between depressive symptoms and premenstrual negative affect implies an intricate relationship between depression and the behavioral symptoms that women experience during the luteal phase of the menstrual cycle.

Significant Alterations in Symptoms Occur during the Premenstrual Phase

Many public health concerns related to depression increase in prevalence during the premenstrual phase of the menstrual cycle. Studies have shown that of the rate of hospital admissions, suicide attempts, completed suicides, and calls to suicide prevention hotlines is higher in women during the premenstrual phase than during other phases of the menstrual cycle [13]. Furthermore, up to 50 percent of premenopausal women who are admitted for psychiatric care are in the premenstrual or menstrual phase [14]. These data identify the premenstrual phase of a menstruator's cycle as a critical window for mental health crises intervention.

It is plausible that not only are rates of suicide and other extreme events exacerbated during the premenstrual phase, but also depressive disorders at large may be intensified as well. In fact, rates of premenstrual mood-related symptoms in menstruators with depressive disorders are higher than in those who do not suffer from a mental illness. In an extensive cohort study, 68.5 percent of over 1700 women who had been diagnosed with MDD reported premenstrual mood-related symptoms [15]. Furthermore, the presence of premenstrual mood-related symptoms significantly predicted the incidence of both postpartum and perimenopausal symptoms in women with MDD [15]. It appears that depression manifesting as premenstrual symptoms earlier in life is associated with higher risk of depressive symptoms after childbirth and during perimenopause, menopause, and after menopause.

Age at Menarche Influences Depressive Disorders

Harlow et al. detailed the significant association between age at menarche and depression [16]. Participants were recruited for the Harvard Study of Moods and Cycles,

and 332 women ages 36 to 45 years from the Metro-Boston area met the criteria for diagnosis of MDD [16]. Age at menarche was inversely related to risk of depression ($P < 0.001$). Compared to women reporting menarche at age 12, women who had their first menses at age 10 or earlier were 2.4 times more likely to be diagnosed with MDD. In contrast, women with menarche at age 15 or later had a marginally significant 40 percent lower risk of MDD.

Similar findings have been reported in studies outside of the United States. A retrospective cohort study of 4,391 women aged 30 and older used data from the Finland Health 2000 survey to examine the role early age at menarche plays in mental health [6]. Symptoms and incidence of depression and general health were assessed using the Beck Depression Inventory (BDI-21) and General Health Questionnaire (GHQ-12). The participants were also asked to recall when they had their first menses and to assess the regularity of their current menstrual cycle. A younger age at menarche was associated with higher risk of MDD and with higher (i.e., worse) scores on the BDI-21 and GHQ-12 ($p < 0.01$). Younger age at menarche had significant negative correlations with feelings of past failure ($p < 0.001$), sadness, dissatisfaction, punishment, lost interest in other people, and looking ugly ($p < 0.01$). Negative correlations were also found with some indicators of general health; as age at menarche decreased, feelings of strain, depression, and unhappiness increased ($p < 0.01$).

Menstrual Irregularity Affects Depression

Other menstrual characteristics, aside from age at menarche, have also been assessed for their role in the risk of depression later in life. For example, Harlow et al. assessed menstrual symptoms that occurred during the first five years after menarche in order to discover any potential relationships between early menstrual characteristics and their effects on MDD development [16]. Of the menstrual symptoms considered, cycle irregularity (OR = 1.5) and moderate to heavy flow (OR = 1.6) were moderately associated with risk of later depression. A different study found that in women aged 30 to 55 years old who were not using hormonal contraception, irregular or absent menstrual cycles was associated with higher experience of symptoms of depression ($p < 0.001$) [6].

Premenstrual Exacerbation of Symptoms of Depression

In addition to age at menarche and irregular cycles, premenstrual exacerbation of depressive symptoms in menstruators is a well-documented phenomenon. Premenstrual exacerbation (PME) is defined as the worsening of an existing psychiatric condition, in this case depression, during the window of five to ten days prior to onset of menses [14]. PME is highly prevalent in women with MDD and has significant effects on symptoms of depression [14, 17]. In a study seeking to determine the rates of PME in different psychiatric disorders, 52 percent of women with depression who reported premenstrual symptoms specifically experienced PME of their depressive symptoms ($p < 0.005$) [14].

In one study, 58 women with depressive disorders were followed prospectively over two menstrual cycles for menstrual symptom exacerbation [13]. Insomnia/hypersomnia, appetite loss/overeating, fatigue, and feelings of worthlessness were each significantly exacerbated during the premenstrual phase. In addition, 58 percent of the women experienced a worsening of one or more of their depressive symptoms during the premenstrual phase, with a mean of 1.34 symptoms worsened [13].

Clinical features and avenues of treatment for MDD have been explored in the Sequenced Treatment Alternatives to Relieve Depression (STAR*D) study, introduced in 2003 and supported by the National Institute of Mental Health [18]. Patients enrolled in this study were recruited from 55 clinical sites and were all seeking treatment for depression, creating an avenue for inquiry regarding the role of these patients' menstrual cycles in their illness [17]. Participants included 433 premenopausal women with diagnosed MDD not taking oral contraceptives.

Of the 433 participants, 64 percent reported premenstrual exacerbation of their depressive symptoms in the five to ten days prior to their menses [17]. This finding is consistent with other reports of PME prevalence in the majority of worsened symptoms in this cohort were somatic. The most reported PME-associated symptom was somatic pain ($n = 227$, $p < 0.0003$), followed by mood reactivity ($n = 188$, $p < 0.045$) and psychomotor slowing ($n = 180$, $p < 0.009$), which is described as the retardation of both thought processes and physical movement [17]. Both gastrointestinal symptoms ($n = 133$, $p < 0.006$) and leaden paralysis, or the sensation of weighed down limbs ($n = 132$, $p < 0.001$), were also significant. Furthermore, the length of the current depressive episode in those who reported PME was significantly longer— a mean of 30.6 months versus 13.2 months in women without PME ($p < 0.001$) [17]. Thus, not only were the symptoms of depression worsened in this population, but women experienced MDD for a longer period of time. These results demonstrate that women may experience substantial physical symptom burden, as well as emotional symptom exacerbation, as a result of the comorbidity of depression and menstrual symptoms.

A second study by the STAR*D investigators attempted to replicate these initial findings. The second cohort consisted of 821 women who were receiving outpatient treatment for MDD and not taking oral contraceptives [19]. Of this cohort, 66.3 percent of women reported PME, again demonstrating the broad prevalence of this phenomenon. Severity scores on the Cumulative Illness Rating Scale (CIRS) were significantly higher in women with PME ($p < 0.001$), suggesting that PME is associated with a greater medical burden overall, beyond depressive disorders alone.

Results from the STAR*D study also suggested that there was a slight but significant difference in the ages of women who reported PME, with those who reported PME on average older than those who did not report PME [19]. Other studies have found similar associations of age and PME. In a community-based cohort of women and girls in the United States, women aged 34 to 53 were more likely to experience PME than those aged 13 to 33 [13]. The study determined that women aged 34 to 53 were about 2.6 times more likely ($OR = 2.59$) to have at least one symptom of depression exacerbated during the premenstrual phase of her cycle than younger women. In fact, this study found that age was the single best variable to use to predict the number of symptoms exacerbated ($\chi^2 = 10.93$, $p < 0.001$).

DISCUSSION

From these data, several key conclusions can be drawn. First, there is a significant public health burden resulting from the comorbidity of menstrual symptoms and depressive disorders. Numerous studies have shown that the premenstrual phase of a person's menstrual cycle may be a vulnerable time for mental health, including exacerbation of depressive symptoms, hospitalization, and suicidal behaviors.

It is evident that depression is a more dangerous diagnosis for those who menstruate not only because of menstruation's exacerbating effect on depressive symptoms, but also because of the higher prevalence of comorbidity. In a sample of the United States population, a cohort of 11,648 menstruating women ages 18 to 55 was studied to identify menstrual problems related to mental health [5]. Almost 19 percent of the cohort reported premenstrual symptoms or symptoms during menses. Women reporting premenstrual symptoms were 2.5 times more likely to have experienced depression in the past 12 months and 2.5 times more likely to have recurrent pain. From this representative sample of menstruators combined with the numerous other reports from communities across the United States and around the world, it is obvious that the incidence and experiences of depression in menstruators translate into a substantial public health concern.

Targeted approaches for improved clinical care are urgently needed for those people experiencing comorbid depression and menstrual symptoms. This population, already under increased health risk, has also been shown to carry a greater medical burden in general. Studies that incorporated measures of general health status found that menstruators with depressive disorders have worsened overall health and a greater incidence of general illness [6, 19]. These findings highlight a group with increased medical need. To better treat this population, healthcare professionals should be aware of the increased health risks that are associated with depression in someone who menstruates.

Another concern to be addressed is the timing of illness in this population, paying particular attention to the phases of the menstrual cycle. Since it is known that mental health issues are most prevalent during the premenstrual phase, individual care should be tailored to the phase of the menstrual cycle as well. Pharmacological intervention for depression may not address the cyclical exacerbation that occurs during the premenstrual phase; rather, medical treatment has historically been administered continuously throughout the cycle. Improved knowledge of the risks presented in the premenstrual phase may help public health and medical professionals improve future medical care and dynamic treatment regimens.

Finally, age seems to be a critical indicator for targeted treatment and monitoring in this population. Evidence suggests that in younger women, depression may increase premenstrual symptom severity. In contrast, in older women, premenstrual exacerbation of existing emotional and physical symptoms is of greater concern. Menstruation and depressive disorders are intricately intertwined. This relationship is evident across ages, countries, and personal histories. However, despite the high prevalence of these conditions and impact on women's lives, the menstruation-depression connection has not

yet been adequately addressed from either the public health or clinical standpoint. Incorporating the consideration of the menstrual cycle, in phase, severity, and symptoms, into the care of depression and other mental illnesses will increase the quality of life of patients experiencing both menstruation and depression, and will also ultimately benefit the health of all menstruators through an overall improvement in competent care.

Chapter 521

ADVANCEMENT OF BIOCHEMISTRY AND MOLECULAR BIOLOGY IN RELATION TO PUBLIC HEALTH

Mohammad D. H. Hawlader*, PhD

Department of Public Health, North South University (NSU),
Dhaka, Bangladesh

ABSTRACT

Biochemistry and Molecular Biology has been developed as disciplines in this century. Both the Biochemistry and molecular biology together are making a significant contribution to the aspect of population health. In last decade, the health care and delivery system all over the world became systematic and technologically more advanced. The doorway of the new century is a promising time to review the public health advances over the past 100 years. In the twentieth century, there was a significant improvement in public health methods, practice, and health of the general population. For the assessment and promotion of health and ultimately for the reduction of the burden of morbidity and mortality, there is an emergence of invention of new tools. Some of the contributions of Biochemistry and Bimolecular science are prominently notable for their impact on reduction of mortality and prolonging longevity. Many new and ongoing evolutions which are ultimately giving the guidance to develop a comprehensive health care system in the frame of reference of public health. Both molecular biology and biochemistry have the potentiality to achieve extensive environmental, economic and health benefits. There is a contrast between personal health and public health. The personal health attended as separate from public health. Globally the upcoming challenge is to convince the policy makers that personal health care is not the only option to improve health care and delivery system. Furthermore, allocation of funds, either in research, program operation, monitoring and evaluation, are the prime important to be started urgently and immediately with the novel goal to improve health for the entire population of the world. So public health incorporation with laboratory techniques will be more effective approach to combate future health challenges.

Keywords: biochemistry, molecular biology, public health, advancement

INTRODUCTION

Biochemistry and Molecular Biology has been developed as disciplines in this century. Both the Biochemistry and molecular biology are making a significant contribution to the aspect of population health (Campbell P 1992). In last decade, the health care and delivery system all over the world became systematic and technologically more advanced. The doorway of new century is a promising time to review the public health advances over the past 100 years. In the twentieth century, there was a significant improvement in the method and practices of public health and also the health of the general population. There is also facilitation for effective understanding of the disease process to find out more scopes of prevention through advancement of different methodological approaches. There are stepwise advancement of epidemiological methods, lacking behind the study of the determinants of health. As a result, there is a simplistic formulation of correlating risk factors associated or contributing to different types of diseases, injuries and wellbeing of mankind at the community level, national level and globally (National Academies Press US 2002).

For the assessment and promotion of health and ultimately for the reduction of the burden of morbidity and mortality, there is an emergence of invention of new tools (Sanjiv Kumar 2012). In turns, it will ensure the effective interventions and estimations of the economic effects of different types of investments which will provide the greater efficiency and will be able to provide a comprehensive effective public health programs. To confront unprecedented challenges in public health, including rapidly growing global population, increased number of aged population, and some unprecedented changes in key environmental health indicators, there is an unavoidable need for fragmentation of infrastructure of the public health (Fielding JE 1999).

Some of the contributions from Biochemistry and Molecular Biology sciences are remarkably notable for their impact on reduction of mortality and prolonging longevity. Those are, invention of new vaccines, complete eradication of smallpox, remarkable reductions of communicable disease epidemics, and controlling over several chronic diseases. So many advancement enabled the understanding of basic disease mechanisms and provided tools to measure health in better ways and finding out appropriate intervention (Robert J. A 2010). Progressive advances of invention in public health arena are many, however few of those can be described in brief.

ADVANCES IN METHODS

In last decade, positive progresses in advancing public health has been achieved. Through the remarkable advances of the last few decades in the field of biomedical sciences, it gradually entered from basic biological science through clinical research to comprehensive public health services. These developments have gone through the transformation of both large and small-scale biological and biomedical researches in a dramatic way (National Academies Press, US; 2003). Laboratory and clinical investigations are most essential

components of health sector. There are several scientific breakthroughs which have important contributions in public health perspective in a way of how research is conducted. After gaining knowledge from population-based epidemiological studies and clinical trials, integration and correlation of knowledge regarding molecular research is important for the public health researchers. From where they are guided to learn what works and what does not work, what is safe and what is not safe. Now a days, there is an increasing demand for focusing on multidisciplinary research including genetic variation, cell dynamics, and metabolic, nutritional, environmental, and pharmaceutical variables. Also greater emphasis must be given on behavioral social sciences and health services research for more effective treatment of diseases and improvement of quality of life (Nass SJ 2009). New and ongoing evolutions which are ultimately giving the guidance to develop a comprehensive health care system in the frame of reference of public health are:

CRISPR Genome Editing Has Foreseeable Implications for Plastic and Reconstructive Surgery

The CRISPR (a family of DNA sequence) genome editing technique is affectively used in almost every branch of medicine now a day. It is the new era of “transformative leap” in genetic engineering and treatment (<http://home.lww.com/news.entry.html/2018/10/30>).

Scientists Investigate How Broad-Spectrum Antibiotic Therapy Affects Interaction of Gut Bacteria

Billions of beneficial/symbiotic bacteria habitats in human gut. They play active roles in digestion of foods, activating the immune system and helping in production of vitamins. But antibiotic therapies usually destroy these gut bacteria. Side by side, their presence facilitates the spread of pathogens which is called opportunistic infection. These intestinal micro biome, is prone to disruptions. When the gut bacteria is out of balance, then the risk of infection increases and the diabetes become more prevalent, as well as inflammatory and neurological diseases (<https://www.news-medical.net/news/20181107>).

Scientists Discover Cell Adhesion Mechanism Used by *Mycoplasma genitalium*

Globally, *Chlamydia trachomatis* bacterial infection is one of the most common causes of sexually transmitted infections (STI). It infects the human cells; by the mechanism of hijacking some parts of the host cell to create defensive layers around the *Chlamydia trachomatis* (<https://www.news-medical.net/news/20181029>).

Genetic Defect Linked to ALS Causes Sugar-Starved Cells to Overproduce Lipids

A variety of diseases like neurodegenerative and mental illness can changes in the pathways of lipid metabolism in the sugar deprived cells. A new study led by a group of researchers from the Bloomberg School of Public Health, Johns Hopkins University shows the findings could lead to new targets to treat these diseases, currently those have no cure or effective treatments (<https://www.jhsph.edu/news/news-releases/2018>).

Cryo-Electron Microscopy Helps Study Proteins Responsible for Amyloid-Based Diseases

In the past century, the aim was to understand the contribution of protein with amyloid-based diseases such as, Huntingdon's, Alzheimer's and Parkinson's diseases. Lots of initiative and steps have been taken in the last one year. There is a great revolution by the scientists to use a powerful microscopy technique (<https://www.news-medical.net/news/20181030>).

Insights into Tumor Initiation Pave Way for New Skin Cancer Treatments

In case of melanoma; the salient vulnerability is discovered by the researchers. It was found that the melanoma-specific long non-coding RNA SAMMSON in tumor initiation was responsible for melanoma. According to the researchers, it stimulates the protein synthesis in different cellular compartments. This threat begins when there is modification of protein synthesis from normal cells (<https://www.news-medical.net/news/20181029>).

Insulin Discovery Could Improve Treatment for Diabetes

Now a days, a group of researchers discovered the therapeutic Insulin through an international collaboration at the Walter and Eliza Hall. This therapeutic insulins are more effective. It is better as resembling the way actually insulin works in human body (Charilaos S 2009).

Salk Researchers Advance Sonogenetics Technology for Treating Neurological Conditions

Recently the technology of sonogenetics has been emerged. In this technique, cells are controlled by sound. It will open a new era where incase of epilepsy, PTSD (post-traumatic stress disorder), Parkinson disease, the pharmaceutical drugs or invasive surgical treatments can be replaced by sonogenetic technology (Stuart I 2015).

Understanding of Metal-Free Enzymes Used by Bacteria Could Lead to New Effective Antibiotics

In case of some bacterial pathogens, it is observed that, *Streptococcus pneumonia* has the ability to generate the components mandatory to replicate their DNA without the presence of any required metal ions (Jose M 2016).

Stem Cell Treatments for Chronic Disease and Anti-Aging

“Alarm signals”: The term indicates the process of self-repair. The living organisms have stem cells both centrally and peripherally. These stem cells can be mesmerized to sites of injured tissues. In this manner, these cells ultimately go through the proliferation, migration, and accumulation process at injured or damaged sites gradually. With the sustention of this condition of “alarm,” the stem cells become exhausted permanently. That ultimately leads to irreversible disease transformed from their original locations. Basically, it depends upon the quantity of stem cell and during active regeneration, on its effective availability until a certain time period. The function of these adult stem cells therapy is the re-population of the stem cell pool. Ultimately, this improves the immune system. The presumed consequences of this fact could be the insufficiency of an adequate amount of stem cells for the tissue replacement and regeneration. Which in turn responsible for development of diseases and ageing. An irreversible and premature stem cell exhaustion could be promoted by this process. So, in turn, make the self-repair and survival process of organism impossible. As we grow older, our circulating stem cells become diminished. So the existing cells to our body’s circulation can improve health and repopulate our stem cell pool by introducing new stem (Anastasia Y. E 2015).

Researchers Closer to Gonorrhea Vaccine after Exhaustive Analysis of Proteins

In a study of proteins, November 8, 2018 Oregon State University researchers have reached closer to an invasion of vaccine for gonorrhea. Also proceed towards interpreting why the bacteria that cause the disease are so good at shielding off antimicrobial drugs (<https://www.sciencedaily.com/releases/2018/11/181108105945>).

The Food Biochemistry

Focuses on different ideas and schemes to intensify the knowledges and understanding of composition of foods, and particularly give emphasis on food components that have beneficial effects on health. The Food Biochemistry encompasses the implementation of different method including both chemical and biochemical analytical methods of food components [20]. It also focuses on their reactions, model systems, and various statistical

tools for data analysis efficiently to find out the maximum informative value. And finally apply those knowledges on public health sector.

Recent scientific era has witnessed that there is progressive development in the fields of biotechnology and biochemistry which leads to a tremendous success in the field of medical and public health science. The achievement and advancement created in the domain of biotechnology has resulted in evolution of newer classes of potential drugs. Lots of newly designed subunit vaccines are developed from the contribution of expression of various prophylactically important proteins, polypeptides and cloning. New techniques are constantly being introduced leading to production of phenomenal and curative molecules which help in diagnosis of different diseases, invention of preventive measures and eventually unveiling the ways to cure the diseases (<https://www.encyclopedia.com/food/encyclopedias-almanacs-transcripts-and-maps/nutritional-biochemistry>).

Vaccination

Recently DNA vaccines have been introduced in the arena of vaccinology, as a new prophylactic strategy enriching the public health sector. The genetic material expresses an antigen which is originated from pathogen. It plays a role to activate host immune system. Plasmid administration, is the main involving strategy (Kishwar H 2013). This plasmid usually conform of a strong viral promoter which drive the transcription and translation of the gene in vivo. The superior one is multicistronic vectors that have the potentiality of expression of more than one immunogen. Sometimes it expresses an immunogen and also an immunostimulatory protein. Definitely this multicistronic vectors are better than those that can express only one protein.

Treatment of Genetic Disorder

During the past decade, there has been a breakthrough in the field of genome editing and genome regulation. It made a remarkable easier way of involving various technologies. Among them, the CRISPR 9 bacterial system, one of the recently adopted technologies, which has evolved as a simple, RNA-guided phenomenon (Gupta R. M 2014). This is used for an efficient and specific genome editing and regulation in case of both bacteria as well as higher eukaryotes. The technology is emanated as a revolutionary tool in biomedical research and field. It has opened a new glimpse for treatment of genetic disorders. The process involves getting the guidance from RNA. The target sequence is opened by the breaking down of the host genome endonuclease. The defective repair mechanism of the generated double strand breakdown process emanates in insertion or deletion mutations. CRISPR mediated engineering usually expedite the initiation of specific point mutations or insertions in the target DNA. By using Cas9 Multiple genomic loci can be efficiently altered at a time through the introduction of several sgRNAs concurrently. For large-scale chromosomal rearrangements, this approach can be used. This technology is also used to achieve the disease models for genetic disorders. Besides other diseases such as carcinoma, which help us for easy understanding of pathological processes in the aspect of molecular basis (Nejat M 2013).

Treatment of Cancer

Recently, there is a new era of treatment of various types of cancer by the immune-based therapeutics, which is becoming the leading asset in the treatment of cancer. Antibody mediated checkpoint blockades in cell cycle can be used effectively for the management of carcinoma now a days (<https://www.cancer.gov/about-cancer/treatment/types/immunotherapy>). Expression of the programmed death-1 (PD-1) receptor is stimulated by cancer cells, used as an approach to downplay adaptive immune response of the host. Antibody mediated blocking of PD-1 can aid in revitalizing the adaptive immune response against cancer (Han Y 2014).

Antibiotic Resistant

There is imminent upswing of pathogens which are antibiotic-resistant. Side by side, development of new antibiotics has become sluggish even though there is elevated demand for substitute therapeutics (Richard J. F_2014). Now a day's probiotics are providing a promising approach. It provides their efficacy is enhanced by introducing new genetic circuits to deliver drug biomolecules to the specific sites. The term 'designer probiotics' are basically recombinant probiotics, which has the capability to reduce the gap between increasing antibiotic resistance and the inadequacy of new antibiotics. Probiotics are emanating living therapeutic agent. The prototype of probiotics can be used for disease diagnosis and prevention. The best documented effects including intestinal disorders, infectious diarrhoea and diarrhoea associated with antibiotic use, allergic conditions (Maria K 2013).

Zika Virus

Zika virus (ZIKV) belongs to Flaviviridae family. Nowadays, the emerging pattern of Zika virus is considered as a major public health concern. Globally, the researchers gave emphasis on ZIKV pathogenesis. To inhibit Zika virus, DNA therapy may result in an emerging therapeutic or prophylactic intervention. This knowledge will help to identify fixed targets for drug design. In different animal models, lots of studies have highlighted the role of DNA vaccine, inactivated vaccine, and viral-vector vaccine (John J. S 2017). These are capable of producing adequate antibody responses for the protection against ZIKV challenge.

Therapeutic Recombinant Proteins

Very recently, the most example of therapeutic usage of recombinant technology is recombinant proteins. Normally, if there are excess accumulation of protein, it results in their misfolding that ultimately causes the development of inclusion bodies. There are several ways by which one can regulate higher recovery of bioactive protein from inclusion bodies.

Use of Nanotechnology

There is a very important role of nanotechnology in different sectors of medical science. Now a days, some techniques are actually being used in some cases, while some are at different stages of experimentation and some of them are still hypothetical only. There is a revolution of medical science based on the use of nanotechnology. Nanotechnology is a very prospective way for diagnosis and treatment of different diseases of human body. Interesting thing is that, various techniques are assumed in few years back but very recently it is making striking progress towards becoming existence.

Nanocrystalline Silver

A Nano sized metal based formulation is Nano crystalline silver. This product is already marketed in United States and many other region. It exploits powerful antibacterial effect. The ionic silver has a potent antibacterial activity, especially against Methicillin Resistant Staphylococcus Aureus (MRSA) that may contaminate wound dressing. There is a rapid and early growth of Nano medicine marketing (Valentina M 2012). Whereas some are at the stage of clinical trial, while Nano-enhanced drug delivery products are commercially produced in the meantime, moreover there is a progressive development of advanced nanotech-based medical devices in current year. At present, Nano medicine has a large therapeutic areas in the field of treatment of carcinoma. In this aspect, Nano medicine has made lots of contributions. Worldwide Abraxane, Depocyt, Oncospar, Doxil, and Neulasta are used for the purpose of treatment of carcinoma. Nano-enabled medical products are potentially blotting out other forms of medicines and drug formulations. Starting from control of infection to treatment of CNS diseases, cardiovascular disease, even carcinoma as well, Nano-medical products are widely used. According to public health researchers, social and political scientists, hindrance of new molecular biological approaches can be refined by assessing the community health. This is a dreadful but fundamental challenges to analyze a complete dimension of determinants of health of population.

Both Biomolecular and biochemistry have the potentiality to achieve extensive environmental, economic and health benefits. There is a contrast between personal health and public health. The personal health attended as separate from public health. Besides range, drug treatment or establishing a national home visiting program for new families, it is also essential to expand opportunities for awareness, physical activity, reducing illiteracy, school dropout rates and female empowerment. Globally the upcoming challenge is to convincing the policy makers that personal health care is not the only determinant of health. Further allocation in research, program, or evaluation are the prime important to be started urgently and immediately with the novel goal to improve health for the entire population all over the world.

Chapter 522

PROMOTING EFFECTIVE TREATMENT AND PUBLIC HEALTH EFFORTS TO COMBAT USE OF SMOKELESS TOBACCO PRODUCTS AMONG APPALACHIAN MALE ADULTS AND YOUTH

Amber K. Hord-Helme and Donald W. Helme, Jr.

Tobacco use is the leading cause of preventable disease, disability and death in the United States (NIDA, 2014). For every person who dies from smoking, many more suffer from at least one serious tobacco-related illness (ACS, 2013b). Like cigarettes, smokeless tobacco (ST), such as chewing tobacco or snuff, contains nicotine and other chemicals and ST users' exhibit characteristics of nicotine addiction similar to that of cigarette smokers. They also suffer from the same health issues, including cancer, heart disease, stroke and type 2 diabetes (IARC Working Group on the Evaluation of Carcinogenic Risks to Humans, International Agency for Research on Cancer, & World Health Organization, 2007; Piano et al., 2010; USDHHS, 1986; 2002). ST is used primarily among males that live in rural settings (12.8% of rural males v. 5.8% of urban males) (ACS, 2013a; NIDA, 2014). This rate is accelerated compared with rates of tobacco use in general with 27% of rural males versus 19% in large urban areas (ACS, 2013a; NIDA, 2014).

Use of ST products has also shown to increase over time among adolescents; from 11.2% in high school freshmen to a 16.6% increase by seniors (CDC, 2018; Chaffee, Couch, & Walsh, 2015). ST use is also correlated and considered in some cases to be inextricably tied with increased demonstration and practice of high-risk behaviors and use of other substances such as other types of tobacco products, alcohol and more illicit drugs. (Levant, Wimer, Williams, Smalley, & Noronha, 2009; Meyer, Toborg, Denham, & Mande, 2008). It is imperative to address ST use in Appalachian populations in order to prevent tobacco use and other high-risk health behaviors.

Why do young males, especially Appalachian males, initiate ST use? Helme et al. (2012) and Nemeth et al. (2012) identified male gender norms and identification as primary paths to initiation of ST use. ST use has overwhelmingly been shown to be a white male phenomenon

that often occurs in the presence of other males, especially in rural areas and/or contexts that are considered male-focused - including traditionally male sports, recreational activities and occupations that are commonly valued as masculine in Appalachian culture (Chaffee et al., 2015; Nemeth et al., 2012). To further complicate the situation for adolescents, the tobacco industry has begun developing dissolvable tobacco chew products that do not have to be spit, and put them into convenient packages that are considered more discrete (Liu et al., 2014). This has enabled students to utilize ST products in schools without being detected.

It is imperative for research and prevention and treatment strategies to incorporate culturally sensitive and culturally informed methods to specifically target Appalachian males. With this population, traditional tactics to increase awareness, prevent initiation and promote cessation are not necessarily effective and, in some cases, would be considered contraindicated (Levant et al., 2009). Campaigns and treatment efforts must include appreciation aspects of traditional Appalachian male identity, family structures, and history in developing effective prevention of initiation and use of smokeless tobacco products.

INCREASED RISK FOR MALES

When considering men in health research, it seems illogical to diminish the role of gender-culture in men's health-related behaviors. Men are much more likely to begin using ST when they are with other men than when they are with women (Chaffee et al., 2015; Cohen-Smith & Severson, 1999; Couch, Darius, Walsh, & Chaffee, 2017; Helme et al., 2012; Nemeth et al., 2012; Ng, Weinehall, & Ohman, 2007; Norberg, Malmberg, Ng, & Broström, 2015). They are also more likely than women to believe that they are not at risk for problems related to ST (Courtenay, 2000). It is also important to note that men cited male peers as being most influential in their decision to initiate use of ST (Helme et al., 2012).

Historically most tobacco control efforts have been focused on educating the public (men and women) about the dangers of cigarette use and persuading them to cease tobacco use. There has been less focus on educating men specifically and persuading them to quit use of smokeless tobacco or e-cigarettes (Helme et al., 2012). Researchers have frequently employed the health belief model, the Transtheoretical model and the theory of reasoned action to predict what makes people more likely to engage in health-promoting or threatening behaviors. Critics note that certain variables used to model men's tobacco use, including age, race, and socioeconomic background are distal and possibly inconsequential to men's decision-making and health behaviors (Levant et al., 2009; "PsycNET," n.d.). This emphasizes the need for inclusion of male-specific foci in tobacco prevention efforts. Research suggests that masculinity is a critical, but largely unexplored factor for why men use ST.

The combination of the Masculinity Theory (MT) (Connell & Messerschmidt, 2005; Courtenay, 2000, 2003) and the Theory of Reasoned Action (TRA) (Fishbein & Ajzen, 1975) clarifies ST use among adolescent and adult males. MT as a theoretical approach frames masculinity as a social product that men institute through interaction rather than as an inherent characteristic of individuals (West & Zimmerman, 1987). From this perspective masculinity is not a given. Instead, men must work actively and collaboratively to assert and "prove" their manhood. Scholarship in this area suggests that proving masculinity typically

involves competition for dominance, risk-taking, emotional regulation (and sometimes suppression), displays of toughness, and (hetero) sexual prowess (Connell & Messerschmidt, 2005).

Competition and posturing among men-adolescent males in particular-establishes a hierarchy of masculinity. Within this hierarchy, those closest to the most dominant “hegemonic” ideal extract the most symbolic and material rewards (Pascoe, 2005). The exact features of this hegemonic ideal and the resources available to obtain it may vary according to time and place. Research on men and masculinity confirms that men actively police the masculinity of other men, holding others “accountable” for non-normative behavior and sometimes encouraging hyper-masculine displays (Kimmel, 2012). This competitive accountability can produce harmful collective behavior such as heavy drinking, sexual assault, bullying, substance use and other high risk behavior to demonstrate manliness to peers (Courtenay, 2000; Schrock & Schwalbe, 2009).

The Theory of Reasoned Action (TRA) (Al-Suqri & Al-Kharusi, n.d.; Fishbein, Ajzen, Albarracín, & Hornik, 2007) has a long history of utility in tobacco prevention and cessation research. TRA essentially formulates how the combination of attitudes, norms and motivation comply with behavior change to predict behavioral intentions. These intentions predict one’s future behavior change. MT and TRA together may better identify, explain, and provide solutions for male (particularly rural Appalachian male) attitudes about tobacco use. Appalachian men’s perception of the beliefs, opinions and attitudes of important others (particularly peers and older male family members) admired or emulated males and attitudes of important females, such as girlfriends, mothers, grandmothers, etc. are factors that contribute to or predict initiation and continued use of ST, and possibly assist in informing interventions to encourage cessation.

INCREASED RISK FOR APPALACHIAN MALES

Why are there excessively high numbers of youth and adult males using ST in Appalachian rural regions? What makes this male population particularly susceptible to initiation and continued use of ST? There is a confluence of factors with regard to cultural/community influences including targeted advertising, excessive exposure and access, and other risk-factor correlations that effectively promote the use of ST in larger numbers of Appalachian men when compared to the general population.

According to Nemeth et al. (2012) and Helme et al., (2012), the use of tobacco products appears to be a “rite of passage” in the development of masculine identity among Appalachian youth. Boys that begin using ST are generally following the influence of older male family members or are encouraged to do so by peer groups. Both studies found that in two different regions (rural Ohio and Kentucky) boys emulated current ST users or were actively encouraged to use ST through male family or peer networks which points to an underlying cultural value. “Enumerating cultural beliefs thus becomes a critical step in the process of understanding initiation into tobacco use behavior and developing effective interventions” (Nemeth et al., 2012).

Male-Dominated Occupations and Masculine Recreational Pursuits

The first and perhaps most crucial cultural factor that promotes the development of Appalachian identity incorporates the use of ST in traditional occupations for men in the region. Most male-dominated Appalachian occupations are associated with promoting tobacco use, particularly ST. Meyer et al. (2008) states that “tobacco growing represents an economic mainstay in many communities, a fact that contributes to the acceptance of its use.” According to Obermiller and Oldenick (1994), “The use of tobacco products not only is socially acceptable among mountain men and women but also widely perceived as critical for economic survival.”

Participants in the Nemeth et al. (2012) study observed that “farm boys” would use ST as a replacement for lighting up a cigarette or other smoking products so as to not risk fire around the barns. Another occupation where fire risk becomes a problem, hence promoting the use of ST, is in the coal mines (Meyer et al., 2008). It is noted that the prevalence of ST among coal miners contributes to its acceptability in families and boys will model their fathers’ behavior. Therefore “attacks on the tobacco industry may be effective in certain communities in the nation, but they are likely to be counterproductive in families and communities deeply tied to tobacco cultivation...Many Appalachian communities continue to depend economically on coal...Messages to prevent ST use and treat it in coal mining communities might develop messages that acknowledge and form strategies to cope with workplace influence” (Meyer et al., 2008). Factories are another place of employment where lit smoking products are not allowed, but ST products are not a problem (Nemeth et al., 2012). These industries have largely defined the Appalachian region and given opportunity to men where there otherwise was very little.

Participants in the Nemeth (2012) study commented often about using ST when participating in traditionally male, outdoor recreational activities that bolster their masculine identity. Sports such as hunting, fishing, four-wheeling, and other primarily male sports and recreation pursuits present opportunities for access and exposure which has been shown to increase likelihood of use (Levant et al., 2009).

Rural Masculine Identity Development

From a cultural standpoint, gender roles in locations that emphasize traditional masculine ideology create circumscribed expectations of men that promote risky health behaviors (Levant et al., 2009). The push toward restrictive emotionality, gender role stress and conflict, conformity to masculine social norms, and cultural beliefs/values about risk-taking in masculine identity research has been well-documented (Helme et al., 2012; Levant et al., 2009; Liu et al., 2014; Nemeth et al., 2012). Rural male identity is perhaps particularly susceptible since interpersonal factors are shown within the culture to be the single most influential element in promoting initiation among rural youth and continued use among rural adult males (Helme et al., 2012; Nemeth et al., 2012). These studies advocate the idea that use of ST is primarily promoted through male social networks in these regions. According to Sorenson (2004), cultural understanding of tobacco use is defined by “learned or shared knowledge, beliefs and rules that people use to interpret experience and to generate social

behavior.” An example of this is observed in rural college-age men whose initiation and continued use of ST began during adolescence in the company of other males and was a result of the desire to fit in with and earn the admiration or acceptance of male peers and role models (Helme et al., 2012). To use tobacco and participate in other traditional Appalachian male activities defines what it is to be a man in these communities. Therefore intervention efforts should focus on shifting the perceptions of cultural norms and address male social networks as a vehicle in ST initiation.

In addition, many of the men in the Helme et al. (2012) study also reported progressing from initial use of ST-only to use of other tobacco products, initiating poly-tobacco use. This is a finding that is observed in other studies of male smokeless tobacco use patterns and prevalence (Agaku, Ayo-Yusuf, Vardavas, Alpert, & Connolly, 2013; Arrazola et al., 2015; Cortese & Ling, 2011; Haddock et al., 2001; Liu et al., 2014; Tomar, Alpert, & Connolly, 2010; Wetter et al., 2002)

Targeted Advertising to Appalachian Males

The tobacco industry has put billions of dollars into researching effective ways to target likely users of ST products. Meyer et al. (2008) reports that an estimated \$239 million was spent by the tobacco industry to research how to market ST products effectively. Many participants in the Liu (2014) study commented on the use of images such as cowboys, lumberjacks, mountain men, timber wolves and similar “manly” motifs to appeal to the masculine ideology. In addition the images on the new dissolvable products are more animated and colorful in order to promote use by younger potential users (Liu et al., 2014). The tobacco industry recognizes that the contribution of traditional masculine ideologies, cultural factors, and male social networking promotes the use of their products. Therefore, prevention and treatment efforts must do the same.

IMPORTANCE OF MALE SOCIAL CONNECTION AND NETWORKS IN APPALACHIA

As discussed earlier, the single most important factor influencing prevalence of initiation and continued use of ST products in Appalachia is the influence of male social networks with peers and family. Helme et al. (2012) highlights the number of participants who spoke about their first and subsequent experiences with use of ST products as being in the context of older admired male family members and peers. Many participants spoke of their first experience of use as adolescents (or even younger) when an older male family member would offer ST as an honor; an acknowledgement of their developing status as a man amidst other men in the community. Despite many of them saying that their first use was distasteful or made them ill, many acknowledged the importance of using ST as a means of continued social acceptance and maintenance/improvement of status among the men (Nemeth et al., 2012).

Most authors acknowledge the importance of family in Appalachian culture. According to Meyer (2008), “kinship influence differentiated it (Appalachia) from the nation.” Since men are often in laborious and dangerous professions that frequently lead to injury, health

problems and disabilities, risk-taking commonly becomes part of the acculturation of young men. When injury, health problems, or disabilities do occur, the importance of family connection and family support in caring for incapacitated loved ones becomes essential (Meyer et al., 2008). The male bonding rituals appear to help foster the cultural values that have allowed families to survive in difficult circumstances.

Common practices in Appalachian homes extend to practiced social behavior within peer networks in communities outside of the home. If ST renders social status among family, then surely social status and connection can be fostered with peers in the same manner. Participants in many studies reported that the prevalence of evidence of ST use in schools and through sports activities are rampant. One participant in Nemeth's (2012) study commented that the "best advertisement is just the people around here...I used it to relax me after varsity football...It's just part of being a young guy around here." A female participant commented about the prevalence of ST spit in the school bathrooms and hallways (Nemeth et al., 2012).

PREVENTION AND CESSATION CAMPAIGNS

The predominate cultural perception is that "everybody does it" (Helme et al., 2012; Nemeth et al., 2012), when in fact only about 12-13% of the male population use ST (ACS, 2013b; NIDA, 2014). Campaigns to prevent use of college students from smoking and drinking have focused on publicizing the actual prevalence of use, which is almost always perceived to be much higher among populations than actually exists (University of Missouri, 2018).

The message that tobacco use is harmful to health is a message that the Appalachian community is already well aware of due to experience with family members suffering from those consequences (Levant et al., 2009). Within families, conflict is often initiated amidst those that are users versus those that are not because of the knowledge of its harmful effects (Meyer et al., 2008) and the greatest influence on ST cessation is due to the power Appalachian women exert on the patterns of use in men. Men often stop because of the wishes of important female figures in their lives such as girlfriends, wives, mothers, grandmothers, etc. Appalachian women are often the spokespersons and guardians of health in their families (Meyer et al., 2008). One participant in the Nemeth (2012) study commented, "The only one I have to hide it from is Mom." A strong influence in promoting cessation is also observed when men become fathers (Meyer et al., 2008).

Rather than bemoaning the harmful health effects of ST, it is more prudent to help families talk about their experiences of the ill effects of ST use. Additionally it is important to target the cultural perception that ST use is a requirement for being a man through the utilization of regular social networks, family and peers. Empowering men who do not use ST to speak up to those who do, or are thinking about initiating use of ST products, is imperative. The connection with family and peers is of utmost importance in the Appalachian community. It is essential that prevention and treatment efforts aim at changing cultural perceptions within existing social networks. This is much more likely to be effective than "professional" outsiders interfering in cultural practices.

Essentially it is the family system and not the individual that will need to be addressed for prevention and treatment efforts to be effective (Meyer et al., 2008). Enlisting women as

health managers of their families (Meyer et al., 2008), accepting the influence of older admired males in the lives of young men (Helme et al., 2012; Nemeth et al., 2012), and addressing the stress involved in the survival of the Appalachian family will likely be the most effective route to preventing this and other health-risk behaviors (Levant et al., 2009) that are common among Appalachian men.

IMPLICATIONS FOR COUNSELING AND PSYCHOTHERAPY

It is very uncommon for Appalachian males to seek professional help in addressing problems associated with smokeless tobacco use. However, it is common for individuals to seek out help for grief and loss issues, coping with chronic health issues, and problems with social isolation. Therefore it is imperative for counselors to recognize that ST use may be a contributing factor to these issues and must be addressed in treatment protocols. Helping clients see the connection between ST use and other health-risk behaviors as a problem so that they can then be empowered to deal with these issues within their communities could have a significant impact on health in the region.

It is also extremely important to take into consideration the cultural factors that influence ST so as not to fall into the trap of using ineffective and contraindicated methods. The family system exerts a strong influence on the behavior of its members and must be utilized in positive ways to be effective in promoting non-initiation and cessation of ST use. Capitalizing on existing knowledge within families about the risks of ST use and its impact on other family members is key. Educating the family system and involving family members in accountability efforts is very effective in decreasing the access and exposure of ST.

CONCLUSION

The impact of socio-cultural norms, traditional masculine ideology, excessive exposure and access, as well as advertising practices are significant in the explanation of increased initiation and use of ST products among Appalachian males in increasingly high numbers. Family systems, approaches to treatment and public health messages targeting ST use may also multiply the impact of the use of other tobacco products, such as cigarettes, cigars, etc. as well as alcohol use and the use of other substances in the region. Cultural perception, values and practices are the key to developing strategic public health and community treatment campaigns designed to decrease the use of ST products.

Despite the entrenched nature of ST use in Appalachia, there is hope for effective intervention strategies. The prevention, cessation campaigns and treatment in the region must be culturally aware and sensitive to the realities of ST use in Appalachian culture. Connection to family and male social networks and norms can be used as advantages in changing cultural perception of ST use. According to Meyer (2008), "Culture deeply influences the perceptions, actions and relationships among individuals who live in a community and profoundly shapes matters of personal and public health. To be effective, the message and its vehicle ultimately need to appeal to the perceptions and realities of the targeted population, and this fact requires consideration of the cultural milieu of that population." Additional research is of utmost

importance in discovering and determining the effectiveness of new treatment and cessation programs and most importantly in identifying and deploying determinants in the initiation of ST use.

It is imperative to become involved in efforts to combat the influence of the tobacco industry in their advertising. Advocating for control of advertising images, convenient packaging that allows for clandestine use, especially by youth, and advertising methods targeted at susceptible populations such as Appalachian male adults and youth is important to protecting an already vulnerable and disenfranchised group that is suffering.

ABSTRACT

This chapter reviews bacteria that deteriorate fish; those that may harm the consumer; fish contaminant bacteria; the risk ranking for consumers; limited bacteria in some legislations and worldwide recommendations; methods and techniques to detect spoilage and pathogens in fish.

Keywords: seafood, bacteria, legislations, human pathogens

INTRODUCTION

The world production of fish and fishery products in 2013 was approximately 160 million tons, and its consumption is estimated at 20 kg per inhabitant per year [1]. Although fish is one of the most sought sources of muscle meat, with high market value, its consumption in Brazil is considerably below the world average. Nevertheless, in the past years an increase of around 14.5% in demand has been observed [2]. Cultural globalization, price reduction,

* Corresponding Author's Email: reginevieira@terra.com.br.

diversity of marketed products, and an ever-growing desire for a healthier diet contributed to a worldwide increase in fish consumption [3].

Due to its high amount of water and the “richness” of its chemical constituents, fish provides an excellent culture medium for bacteria, which make hygiene and temperature parts of the binomial important for its conservation and acceptance. In addition, time (i.e., fast and accurate decision-making) is another factor that, added up to the binomial in our equation, strengthens it, and tends to keep the product from spoilage and decay.

The deterioration process is caused, mainly, by psychrophilic and psychrotrophic bacteria but, above all, the quality of fishery products is measured by the risk of diseases a customer is under by consuming it. Thus, many countries adopt laws and other legislation in order to control fish quality and its products, aiming to protect consumers from any harm they may cause.

BACTERIAL DECOMPOSITION IN FISH

It is possible to describe deterioration as the set of simultaneous autolytic and microbial reactions in an animal right after its death, which originates undesirable compounds/by-products with unpleasant smells and tastes.

Fish might be contaminated with the broadest and most diverse group of microorganisms, through contaminated or polluted waters from estuaries and fishing grounds. The living animal presents bacterial contamination mainly in the skin, gills and scales; and it may spread through other tissues after its death. Therefore, an improper handling and the non-compliance with proper hygienic measures during transportation, handling and storage processes may promote the development of pathogens present in the fish itself or in the environment [4]. Given the difficulty in identifying the source of unpleasant taste and odor in decayed fish, it is interesting to establish standards for fish freshness so that, by making use of a table of attributes, trained panelists are able to analyze products through sensory signals and features. In a parallel analysis, there should be physicochemical tests and bacteriological counts at different temperatures. After these tests, a proper identification of the bacteria responsible for the deterioration should be less arduous. In crustaceans, for example, Vieira et al. [5] described a typical sequence of decomposition while studying lobsters of the genus *Panulirus* White, 1847, in Fortaleza, Ceará State, Brazil. During the first six days of the samples in ice storage, no changes in color, odor and texture of meat were observed. Bacterial counts (log CFU/g) in the muscle at 5 and 25°C did not change considerably. However, on the 13th day of the experiment, some changes were already noticeable. From that day on, meat turned flacid and for the content of total volatile bases exceeded 25 g/100g; trimethylamine reached values above 2.28 mg/100g and panelists rejected the crustaceans. On that day, the Standard Plate Count (SPC) at 5 and 25°C reached 4×10^8 and 8×10^8 CFU/g, respectively, confirming the deterioration by psychrophilic and psychrotrophic bacteria.

Generally speaking, specific spoilage microorganisms (SSO) [6, 7] produce metabolites related to certain smell and tastes of this process. In species from temperate waters, *Shewanella putrefaciens* is a typical dominant microorganism in this particular stage. Bacteria from the Vibrionaceae and Enterobacteriaceae families are also related to spoilage. In tropical waters, *Pseudomonas* have been described as dominant [8]. According to Simmonds &

Lamprecht [9], freshness of ice-stored fish correlates well with sensory analysis, when the counting occurs at 20°C. At this temperature, *Pseudomonas*, *Acinetobacter* and *Moraxella* predominate.

BACTERIA THAT MAY CAUSE HARM TO THE CONSUMER

Seafood is colonized by natural and/or pathogenic microbiota, mostly depending on where it is captured. Some factors that may contribute to an infection by pathogenic bacteria are the presence of sewage and storm water runoffs in the aquatic environment. Diseases related to seafood consumption can be caused by biological, chemical or physical agents. Biological pathogens are represented by a vast amount of bacteria, viruses and parasites [10]. According to Huss et al. [11], pathogenic bacteria detected in seafood and its related products can be divided into three groups: 1) those normally present in the habitat of the species: belonging to the *Vibrio* genus (*V. parahaemolyticus*, *V. cholerae*, *V. vulnificus*), *Clostridium botulinum* Non-proteolytic serotype E, *Plesiomonas shigelloides* and *Aeromonas* spp.; 2) those generally present in the environment: *Listeria monocytogenes*, *Clostridium botulinum* proteolytic type A and B, *Clostridium perfringens* and *Bacillus* spp.; 3) those that usually have man and other warm-blooded, terrestrial animals as their natural habitat (*Salmonella* spp, *Shigella* spp, *Escherichia coli*, *Campylobacter jejuni* and *Staphylococcus aureus*). In order to control these bacteria and prevent them from contaminating products derived from fish, it is of utmost importance to know their origin, biology, physiology and ecology; as well as their survival and growth within the products related to the diseases with which they are associated [10].

In the following sections are described relevant microorganisms; types of fishery products, where they have been most frequently observed/found are pointed out; and incidents in Brazil and/or Latin America are detailed.

Group 1: Bacteria Normally Present in Fish Habitats

Vibrio parahaemolyticus is part of the Vibrionaceae family. They live only in brackish or seawater and are known to cause gastrointestinal illness in humans. *V. parahaemolyticus* is a natural inhabitant of coastal warm waters; in countries with colder weather they are present in higher concentrations during summer; it is a halophilic organism (i.e., organisms that thrive in environments with very high concentrations of salt). Moreover, as a mesophilic organism it is eliminated from seafood by exposing it to heat. When seafood is served raw (e.g., oysters, mussels, sushi, sashimi and/or Carpaccio), its consumers are under risk of infection [8]. The illness' symptoms usually start within 24 hours of ingestion. Illness is commonly self-limited and known to last for up to 3 days. Severe disease is rare, occurring with higher frequency in people with weakened immune systems. *V. parahaemolyticus* may cause infection on the skin when an open wound is exposed to warm, contaminated seawater [12]. According to Boutin et al. [13] *V. parahaemolyticus* intrudes and invades with considerable impact and may spread throughout the body via the circulatory or lymphatic system, causing septicemia. Mahmud et al. [14] stated that the consumption of seafood products may pose risks to public health, since

toxigenic strains of *V. parahaemolyticus* (O3:K6) have been isolated from those sources, demonstrating pandemic potential. In Fortaleza, Ceará State, 26 individuals were involved with an outbreak of gastroenteritis after eating raw crab claws in a restaurant of a hotel where they were hosted. *V. parahaemolyticus* O3:K6 (Kanagawa positive) was confirmed in six samples among nine sent to The Oswaldo Cruz Foundation (Rio de Janeiro) [15]. Despite the low number of reported cases involving *V. parahaemolyticus*, detection of pandemic clones with high potential for virulence in northeastern Brazil and the high temperatures of the region are factors that favor the spread of these bacteria [16]. *V. parahaemolyticus* produces an enterotoxin similar to the one produced by *V. cholerae*, which is able to inflame the epithelial lining of the small intestine. In almost 1/3 of the cases, the diarrhea has bloody form [17]. Vieira et al. [18] while working with oysters purchased at a local restaurant in Fortaleza, Brazil, identified urease-positive and also *tdh* and *trh* positive *V. parahaemolyticus*, concluding that oysters served at restaurants in State of Ceará may cause gastroenteritis to the costumers. In Brazil, *V. parahaemolyticus* was recorded as etiologic agent in several cases of intestinal infection associated with the consumption of, crustaceans and shellfish [10, 19]. The first reference to the isolation of *V. parahaemolyticus* (O5:K17 sorotype; Kanagawa-positive) in Brazil was made by Hofer [20] in diarrheal stools from a six-year old child in Cascavel (State of Ceará).

Vibrio cholerae and *V. vulnificus*, as *V. parahaemolyticus*, also belong to the group of species that cause vibriosis naturally lives in brackish or marine waters but there is no mention to them in the legislation, neither in Brazil nor the European Union. They may infect fish and if product is consumed raw or not properly cooked, may also be transmitted to the consumer. In fact, if the *Vibrio cholerae* belongs to the serotype groups O1 and O39 it might transmit cholera, an epidemic disease characterized by abundant diarrhea.

Vibrio vulnificus is homologous to *V. parahaemolyticus*, differing only on the ability to ferment lactose. It may cause septicemia and eventually death, via ingestion or the bloodstream - reaching through the intestinal tract or open wounds exposed to contaminated marine environment [21].

C. botulinum is widely distributed in the soil and aquatic environments worldwide. It has the ability to produce the most lethal toxin, known as botulinum toxin (BoNT). Seven types of this toxin, from A to G, are known [22]; toxin E is usually associated with the consumption of marine fish and fish/seafood products [23] because its spores tend to be more confined to water, especially seawater [24]. Spores of *C. botulinum* -non-proteolytic type E can germinate at temperatures below 3°C and are often found in association with stocked marine fish [25]. The first botulism outbreak on record in Brazil was in 1958 in the State of Rio Grande do Sul: nine people died after having ingested fish using homemade preservation techniques [26]. In 2007, an isolated case of botulism - again for the same reason - occurred in city of São Paulo [27].

Clostridium botulinum serotypes E, A and B, proteolytic and non-proteolytic, are not contemplated by current guidelines (or regulations or legislation) in Brazil, only sulphite-reducing clostridia (Resolution 12 by the Brazilian Health Surveillance Agency, Ministry of Health [28]). The authors decided to include them all in one item only (Tabela 1). *Clostridium botulinum* is cited, but not limited, by FDA and CODEX.

Proteolytic types A and B of *C. botulinum* were found in samples from areas above Chesapeake Bay (USA) and in samples of fresh blue crab meat (also in the USA) [29]. During 2007, in Brazil, a case of botulism linked to the consumption of homemade canned

fish was reported in São Paulo State. The case was confirmed and related by the Center of Epidemiological Surveillance of São Paulo [30]. Zadeh et al. [31] reported a case of a 12-year old that developed symptoms of weakness and diplopia six hours after the ingestion of barbecued caviar, a fish roe product. Immediately, serum, gastric and stool samples were sent to the Pasteur Reference Laboratory (France) for botulinum toxin detection. Based on the clinical report, the patient received three monovalent antitoxins: A, B and E; and progressively evolved to better health state within 10 days. In Argentina, 21% of the cases of botulism recorded between 1980 and 1989 were related to the consumption of fish and fish products [32].

Plesiomonas shigelloides belongs to the Enterobacteriaceae family, with its primary habitat being warm water environments and fish from both freshwater and seawater. *P. shigelloides* is a Gram-negative bacillus with a positive oxidase test [33]. Ingestion of *P. shigelloides* may not always be a cause of diseases to its host, but the microorganism may remain as a non-infectious, transitory member of the intestinal microbiota. The disease caused by *P. shigelloides* is gastroenteritis, which is usually self-limiting, and yields fever, chills, abdominal pain, nausea, diarrhea or vomiting. The bacteria may be invasive and produce toxins [34]. They are not considered in any global regulation. This bacterium has been isolated from the tissue of fresh and pre-cooked mussels from a farm in Niteroi, Brazil [35]. Infections have been associated with travel to or residence in tropical and subtropical countries, with the consumption of raw seafood or with exposure to amphibians or reptiles [36, 37].

Aeromonas spp. are Gram-negative microorganisms, rod in shape but with a slight resemblance to cocci – straight but with rounded ends. They are catalase and oxidase positive, reduce nitrate to nitrite and ferment D-glucose with acid/acid and gas production. In addition, they are mesophilic and resistant to the vibriostatic agent 2,4-diamino-6,7-diisopropyl-pteridine O/129. They are found in aquatic environment, both clean and/or contaminated with waste and disposal from sewer systems. After ingestion, they may cause intra and extracellular infection. In Brazil, a case of mild diarrhea was reported after the consumption of a shrimp cocktail, and *A. hydrophila* was isolated from both the incriminated food and the patient's stool samples. Both isolates had identical ribotypes [38]. *Aeromonas* are frequently isolated from fish [39] and mollusks [40]. They usually contaminate fish due to their ubiquity in aquatic environments, with several genospecies described as pathogens of fish and humans [41].

Group 2: Bacteria Generally Present in the Environment

Listeria monocytogenes is a mobile, Gram-positive bacterium which grows at 37°C but at the same time is both psychro and halotolerant [42]. *L. monocytogenes* has been isolated from processed marine products (cooked and frozen), marinated fish, surimi, sushi and smoked fish and it is able to rapidly grow in brined shrimp and cold smoked fish. The bacterium is of little importance in semi-preserved fish products when using 2.5% acetic acid. The freezing process eliminates these bacteria, and certain levels of acid and NaCl prevent its growth [43]. However, Hofer & Ribeiro [44] studied and found *Listeria* in samples of frozen *Penaeus subtilis* and *Xiphopenaeus kroyeri* shrimps in Brazil. From a total of 45 frozen shrimps, *L.*

innocua serotype 6a was found in three samples and *L. monocytogenes* in four; 1/2a in three samples and 4b in one. Furthermore, Laciari et al. [45] reported the presence in 50 samples of fish, 22 samples of squids and shellfishes, the isolation of *L. monocytogenes* in a sample of squid and *L. innocua* in a sample of mollusk. No fish sample showed the presence of *Listeria* spp.

Clostridium perfringens is an anaerobic, Gram positive, mesophilic, spore-forming bacterium distributed in the environment; in soil, it is found at levels of 10^2 - 10^4 /g. If high levels of vegetative cells are ingested, they are likely to reach the intestine and sporulate, producing an enterotoxin which may result in abdominal pain, nausea, diarrhea and vomiting in about 8 to 24 hours after ingestion. In the USA, approximately 7 out of 200 reported cases of infection per year are related to consumption of marine fish [46]. Virulent and toxigenic strains of *C. perfringens* were also isolated in unprocessed fishes from freshwater randomly obtained from local sources in Tamil Nadu, India [47]. Poisoning outbreaks caused by *C. perfringens* are especially common in institutions where food is prepared in advance before serving, and preparation conditions favor bacterial multiplication. It is possible to detect *C. perfringens* in foods of animal origin, such as meat and meat products, meat dishes, stews, soups, gravies, and milk. Occasionally, poultry products, pork, lamb, fish, shrimp, crab, legumes (beans), potato salad, and macaroni and cheese may contain *C. perfringens*. These foods at improper storage temperatures provide risk of infection and disease from *C. perfringens* [48]. Since there is no law on mandatory reports of infections by *C. perfringens* in Brazil, there are no cases on record involving fish consumption.

The *Bacillus* species typically responsible for infections, including symptoms of diarrhea and vomiting, is *B. cereus*. Fish, meat, and vegetables are commonly associated with this type of disease transmitted by food. In industrial fish farms in Germany, *B. cereus* was identified in fish from *Clupea* genus after the addition of contaminated seasoning ingredients. The bacilli sporulated after incorrect freezing, a subsequent process that follows pasteurization procedures [46]. In Netherlands, a higher prevalence of psychrophilic strains of *B. cereus* have been reported in meat and meat products (20.8%, n = 24) and in fish and fish products (40%, n = 40) [49]. In Brazil and other Latin American countries, the habit of consuming dishes based on raw fish, with its handling and preparation based on techniques brought from Eastern cultures (e.g., sushi and sashimi) has caused frequent events of intoxication. Rice is an ingredient of sushi, which without proper acidification control introduces the risk of toxin formation by *B. cereus* [50].

Group 3: Bacteria That Usually Have Man and Other Warm-Blooded, Terrestrial Animals as Their Natural Habitat

Salmonella, *Shigella* and *Escherichia* species are fecal bacteria. They belong to the Enterobacteriaceae, having humans and terrestrial, warm-blooded animals as hosts. These microorganisms can contaminate the living animal (incl. fish), depending on the capture site. Further contamination may occur during processing. They may cause serious harm depending on contamination levels but proper cooking eliminates harm. A special attention must be directed to cross-contamination, as well as contamination in work areas (production lines in

industrial facilities for seafood processing, kitchens), and the transfer of microbial pathogens into products that are to be consumed raw [51].

Standards set by Brazilian legislation for *Salmonella* in food is that the organism should be absent in 25 g [28], due to its pathogenicity. However, outbreaks of salmonellosis are not of mandatory notification (except if the case involves typhoid fever), a factor that compromises proper monitoring and investigation of this pathogen. In a study that analyzed the occurrence of *Salmonella* in fish in northeastern Brazil, this enterobacteria was detected in 4% of the samples of fish and shellfish (shrimp and lobster) assessed in the experiment [52].

Campylobacter jejuni are Gram-negative rod-shaped, S-shaped (or of curved morphology) non-spore-forming bacteria that might present a spherical or coccoid form in old cultures. They move by a single polar flagellum at one or both ends [53]. *C. jejuni* and *C. coli* are the most common species of *Campylobacter*, and are usually associated with diarrhea [54]. Although less frequently found when comparing fish to other types of meat, the low infectious dose (500 cells), makes campylobacteriosis one of the most typical zoonotic diseases in human beings [55].

Staphylococcus aureus belongs to the Micrococcaceae. They are Gram-positive round cells, which are found grouped in the shape of grape clusters. They cause food intoxication and are transmitted due to low hygiene standards, during its use and handling. Albuquerque et al. [56] while investigating *S. aureus* in ice, water, benches and in the body parts of sellers and fishmongers (nose, mouth and hands) at a fish fair in Fortaleza, Brazil, identified the bacteria in all surveyed sites, including 100% of the fair shrimp vendors. It was then suggested that there should be more information on adequate hygiene standards and proper handling of the ice for fish refrigeration.

OTHER CONTAMINANT BACTERIA IN FISH AND FISHERY PRODUCTS

In addition to the previously mentioned bacteria, Gelli [57] lists microorganisms able to release histamine (a decarboxylation of histidine), a characteristic that involves mainly fish from the Scombridae family (tuna and bonito). Some histamine-producing bacteria are members of the *Enterobacteriaceae*, along with *Vibrio* sp., *Clostridium* and *Lactobacillus* spp. The strongest histamine producers are *Morganella morganii*, *Klebsiella pneumoniae* and *Hafnia alvei* [58]. In general, biogenic amine-producing bacteria are not part of the marine fish microbiota, their origin is due to contamination by inadequate hygiene habits during capture or associated with a contaminated aquatic environment [59]. Thus, it is possible to affirm that the presence of histamine is also an indicator of bad bacteriological quality [60].

In reference to fermented fish-based products, *Staphylococcus* spp. and *Tetragenococcus* spp. were listed as histamine-producing [61]. Oliveira et al. [59] investigated the presence of histamine in samples of canned tuna and sardines purchased in retail stores in Fortaleza, Brazil, which were analyzed by high performance liquid chromatography (HPLC) in reverse phase. All samples showed the presence of histamine. Levels above 100 mg histamine/kg were detected in 55% of the tuna samples and 13.33% in sardines. The authors concluded that it is necessary to improve the quality of the raw material, and the amounts found in the samples would be able to cause symptoms of poisoning in consumers of fish.

RISK CLASSIFICATION IN A DIETARY FISH CONSUMPTION

Considering aspects of seafood microbiology (afore-mentioned), Huss et al. [62] classified the fish by the risks they might present to its consumers. Accordingly, the highest ranked products in terms of health risks would be the mollusks (fresh and frozen mussels, oysters and sururu i.e., Charru mussel *Mytella charruana*) and raw fish (e.g., sushi, sashimi) or if ingested with no proper cooking, followed by crustaceans and fish, fresh or frozen, which should be properly prepared. Finally, the fish and fish products presenting the lowest risk levels include lightly preserved (salted, marinated, smoked or fermented), semi-preserved (caviar), with proper addition of food preservatives, such as sorbate, benzoate and nitrite, and heat-processed fish, that need to be sterilized and properly disposed into strongly sealed cans.

BACTERIA WITH SPECIFIC RESTRICTIONS AND RECOMMENDATIONS WORLDWIDE

Table 1 presents a comparison of the bacteria used as a standard to assess the microbiological quality in fresh fish and fish products under national and international codes of best practice and legislation. It allows us to compare and analyze the similarities in laws from different countries and their views on bacteria that may pose health risk to the consumer.

Table 1. Bacteria listed in different laws and guidelines concerning the microbiological quality of fish and its by-products

Bacteria listed in laws and guidelines	Source			
	Brazil ¹	FDA ²	EU ³	Codex Alimentarius ⁴
Fecal coliform		X	X	
<i>Escherichia coli</i>		X	X	X ^a
Thermotolerant coliform			X	
Coliforms at 45°C	X			
<i>Staphylococcus aureus</i>		X	X	X ^b

¹ [28]; ² [63]; ³ [64]; ⁴ [65]; ^a pre-harvest and harvest hazards in incoming fish and shellfish; ^b the post-harvest and further processing of fish and shellfish; ^c food for raw consumption.

In general, laws and codes use information related to different stages and conditions in the production, processing and marketing phases: bacteria with pathogenic potential, how they relate to their environmental origins and the quality of the water; bacteria directly related to poor hygienic conditions and their involvement in degradation and loss of food quality. Overall, *Salmonella* is a consensus in the regulations due to the severity of the diseases to which it is related.

DETECTION METHODS FOR PATHOGENS AND SPOILAGE AGENTS IN FISH

In the international market of fish products, quality is focused on two primary aspects: food safety and sensory quality; both, closely related to microbiological parameters. Several methods are used in order to determine and set the standards of freshness and/or quality. Those can be categorized in sensory and instrumental. The latter group encompasses physical, chemical and microbiological methods [66].

Unlike other characteristics, the microbiological parameters do not provide information as to the freshness or palatability of the fish. The purpose of these analyses is to provide a clearer image of the hygienic quality of the product, the hygiene standards during processing and preparation, and the possible presence of bacteria or other microorganisms of importance to public health [67]. Spoilage and deterioration by microorganisms are important sources of disease outbreaks and economic losses. Every year, about one-third of the world's food production is lost as a result of microbial deterioration [68].

In the next sections, culture-dependent and rapid methods are briefly described for further reference on methodologies to assess microbiological contamination in seafood products

Culture-Dependent Methods

Microbiological methods can be divided into detection and enumeration techniques based on classic microbiology procedures, involving selective culture media and incubation periods. Among those classic techniques, it is possible to cite direct counts of culturable bacteria (Standard Plate Count), estimation of bacterial populations (Most Probable Number), counting and detection of bacterial groups and species involved in deterioration processes of fishery products, such as psychrophilic bacteria (e.g., Mol et al. [69]) and histamine-forming bacteria (e.g., Bjornsdottir et al. [70]). Despite (or because of) being classical, these techniques constitute national and/or international standards. As a result, they are still often used in quality control (QC), research and development (R&D). For instance, Lin et al. [71] used culture-dependent methods to isolate and quantify histamine-forming strains of salted fish samples. Moreover, Dalgaard [72] employed quantitative and qualitative tests using culture media to characterize the degrading activity of the microbiota of fish products.

In the case of bacterial pathogens, monitoring may be done by a series of different detection methods. Some are only capable of a qualitative presence/absence confirmation of the pathogen, while others allow the quantification of the bacterial load [73]. For pathogens with zero tolerance criteria in food, there is no purpose in quantifying the bacterial load, but

in case of pathogens that are tolerated below an established limit; the later approach is extremely useful. In this case, conventional plating techniques and cultivation of pathogenic bacteria are still the primary choice to assess the degree and extent of contamination in food products, including fish [74].

There are well-established protocols for enumeration and detection of human pathogens related to fish, such as *Salmonella* spp., *Vibrio* spp., *Staphylococcus aureus* and *Clostridium* spp. In general, the protocol includes a nonselective pre-enrichment step, followed by enrichment in selective medium and a subsequent plating on selective agar plates. Detection of suspicious strains requires further isolation and confirmation by biochemical and serological tests [75].

Quantitative microbial techniques also have the advantage of being adaptable to meet the specific needs of each sample, as well as requirements of target microorganisms [76]. As an example, the use of culture media of different composition and the incubation at various temperatures was the strategy used by Uddin et al. [77] in order to assess the bacterial microbiota of frozen fish imported from Denmark.

However, in spite of the sensitivity of these cultivation methods and their well-established, standardized protocols, they are time consuming and often expensive, requiring specific technical skills to be run. These characteristics make them unsuitable for quick inspections in the case of fish and fish products [78, 79]. Another disadvantage is the difficulty that stressed, i.e., “viable but non-culturable” bacteria have to grow in the conditions created during the tests.

Rapid Methods

Rapid detection of pathogens and analysis of the deterioration processes in food samples is essential to ensure fish and fish-products safety and quality. Rapid microbiological methods have been developed to meet this specific demand from the global food market. In the case of fish and fish-based products, the high perishable nature of these products should be taken into consideration as a determining factor in choosing techniques that offer faster and accurate responses.

The two main groups of rapid methods to detect microorganisms are based on immunological reactions (Enzyme-Linked Immunosorbent Assay-ELISA, monoclonal antibodies) and genetic engineering techniques (Polymerase Chain Reaction-PCR, DNA probes, etc.) [80]. The first group provides faster response while the second group has a higher specificity to detect microorganisms in fish and fish products [81]. Thus, genetic techniques are used more often.

Molecular-based methods, especially those based on polymerase chain reaction (PCR) or microarray have proven accuracy both in quantification and detection of pathogens in fish-based food [82-87]. Research has proven the efficacy of these techniques in detecting pathogens in fish and in tracking sources of contaminants bacteria. Already in 1996, Destro et al. [88] used molecular-typing methods, namely random amplified polymorphic DNA analysis (RAPD) and pulsed-field gel electrophoresis (PFGE), to track the dissemination of *Listeria monocytogenes* in shrimp processing plants. Rørvik et al. [89] characterized *Listeria* isolates using multi-locus enzyme electrophoresis and restriction enzyme analysis of total

DNA to establish the environmental sources of this pathogen in marine fish and industry. Similarly, Mauffret et al. [90] tested real-time PCR to track microbial sources in samples of bivalve mollusks. Shimizu et al. [91] used the Fluorescence *In Situ* Hybridization (FISH) method to rapidly quantify *Salmonella enterica* in food samples, including fish.

These rapid techniques may also assist in monitoring and quantifying bacteria that produce metabolites responsible for off-flavors and cause sensory rejection of fish and fish-based products. Off-flavours are the main indicators used by consumers to evaluate fish freshness [92]. Compounds that produce such characteristic odors, for example trimethylamine (TMA), various nitrogen and sulfur compounds, aldehydes, ketones and esters are produced by a variety of microorganisms during the process of deterioration of fish [93, 94].

CONCLUSION

To conclude, there is a major need from all the stakeholders involved in the process of producing, processing and exporting fish and fishery products to focus on the quality of the products, for only awareness and education will make the food that gets to the consumer a harmless one.

Progress in rapid detection methods for foodborne pathogens, advancements in the fishing gear, dynamic forms on which we are able to communicate and share information in the present days - all these elements foster a standardization and a much more balanced comparison of the different regulations at a worldwide level.

There are, however, two major needs in order to improve the quality and safety of the currently marketed fish and fish products: discipline to comply with the regulations, and a huge effort from governmental agencies. This is particularly true in countries where the level of industrialization of the fishing and processing of fish or the subsequent regulations are newer and/or less consumer-oriented, or little worried about environment issues and sustainability.

THE PRECISION MEDICINE AND PRECISION PUBLIC HEALTH APPROACHES TO CANCER TREATMENT AND PREVENTION: A CROSS-COMPARISON

Stephen M. Modell^{1,*}, Sharon L. R. Kardia² and Toby Citrin¹

University of Michigan School of Public Health, Ann Arbor, Michigan, USA

ABSTRACT

Like other forms of diagnostics, genetic testing comes with a retinue of costs and benefits. Significant benefits in terms of morbidity and mortality have accrued to individuals tested for more prevalent genetic conditions like cystic fibrosis and sickle cell disease, including persons seen in the emergency room or identified through public health surveillance. These benefits do not mitigate the drawbacks of genetic testing, false and missed diagnoses and sheer cost among them.

Both medicine and public health have aimed at means of maximizing genetic test benefits in the interventions that they apply. The President's Precision Medicine Initiative (PMI) holds promise in that its results could be used to tailor medical treatments to the individual characteristics of patients, "precision" implying a more accurate and precise regimen overall. The National Cancer Institute (NCI) has already launched the NCI-MATCH precision medicine trial, which assigns targeted treatments based on the genetic abnormalities in a tumor, regardless of cancer type. Other trials, such as the NCI Pediatric MATCH trial, are yet to happen. The efficacy of cancer treatments also intersects public health concerns. The Evaluation of Genomic Applications in Practice and Prevention (EGAPP) Working Group has evaluated the use of *UGT1A1* genotyping to determine the best dose of irinotecan to prevent side effects when treating patients for metastatic colorectal cancer. Analytic validity does not always equate with improved patient

* Corresponding Author's Email: mod@umich.edu; Tel: (734) 615-3141; Fax: (734) 764-1357.

outcomes, however, thus the public health emphasis on development of a suitable evidence base for precision medical and public health efforts.

The public health approach to precision medicine, or “precision public health”, differs from the medical approach in several important ways: (1) population-based with attention to at-risk populations, as opposed to being strictly individualized; (2) focus on primary and secondary prevention, rather than frank disease (tertiary prevention); and (3) prioritizing interventions that have already demonstrated readiness for large-scale implementation, in contrast to the undertaking of novel clinical trials. Precision public health is exemplified in the Centers for Disease Control and Prevention’s emphasis on the implementation of Tier 1 genetic tests that have passed systematic review for analytic and clinical validity and utility – the use of family history for referral for hereditary breast and ovarian cancer genetic testing (*BRCA1/2* mutations), and hereditary nonpolyposis colorectal cancer cascade screening (Lynch syndrome *MLH1*, *MSH2*, *MSH6* mutations).

This paper will cross-compare the precision medical approach to cancer based on pharmacogenomic regimens using companion diagnostics, and the public health approach to precision management of hereditary cancer for 3 cancer types – lung, breast, and colorectal. It will describe methods of early detection and consider how lives can be saved through precise management – from predictive testing and cancer monitoring of the at-risk population, to tailored chemoprevention that fits the needs of the individual. In the population context, a cascade screening “multiplier effect” exists in that relatives can also be assessed and followed for mutations identified in the proband. Cost-benefit analyses (T4 translational research) of medical and public health approaches will be closely examined and compared. Points of commonality between the two approaches will also be discussed, since primary/secondary and tertiary disease prevention represent a continuum. These analyses point to the value of allocating resources towards the health of at-risk populations. Questions remain if particular forms of genetic testing are to become “universalized”, and if the needs of all at-risk groups, including racial-ethnic, are to be addressed.

Keywords: lung cancer, breast cancer, colorectal cancer, Lynch syndrome, genetic testing, cascade screening, universal screening, cost-effectiveness, precision medicine, pharmacogenomics, public health, race, ethnicity

FROM THE HUMAN GENOME PROJECT TO THE PRECISION MEDICINE INITIATIVE

If the twentieth century is known for its success in mapping the human genome, the twenty-first century is becoming equally well known for scientists’ attempts at making genetic interventions “precise” – appropriately chosen, and delivered to the right person and physical target within the human body. The Precision Medicine Initiative (PMI), launched by the Obama administration in January 2015 with a \$215 million outlay in the President’s 2016 Budget and continuing onward in the current administration, brought medicine closer than ever to the ability to tailor medical regimens to the needs of the individual patient [1]. An article by Francis Collins, Director of the U.S. National Institutes of Health (NIH), and Harold Varmus, former Director of the U.S. National Cancer Institute (NCI), which appeared shortly after the announcement, broke the Initiative into two stages: a near-term focus on cancers, and a longer-term aim to yield new knowledge applicable to the broader range of health and disease [2]. Muin Khoury, Director of the Office of Public Health Genomics at the

U.S. Centers for Disease Control and Prevention (CDC-OPHG), and Sandro Galea, Dean of Boston University School of Public Health, followed-up with the affirmation that the PMI could, in time, be used to develop, evaluate, and deliver health interventions with greater “precision” for both individuals and populations [3].

The distance between a strictly individualized approach to precision medicine and one that is population-oriented, fitting the right intervention to the right population, is transcended by a common denominator shared by medicine and public health – cost-effectiveness. Translational research spans several distinct territories, from basic genome-based discovery as it yields candidate health applications (e.g., new genetic tests and therapeutic interventions) - T1 translational research, to evaluation of real-world outcomes (e.g., morbidity and mortality, cost-effectiveness, and quality-of-life indicators) - T4 translational research [4]. In this piece we take the position that whatever the molecular genetic or behavioral approach used, it must make sense dollar-wise such that the interventions are being mustered in an effective and economical way. Our analysis will show that the criterion of cost-effectiveness naturally shifts the prospect of a national precision medicine effort in the population-oriented direction. Though the two may seem like strange bedfellows, both the pharmacogenomics industry and public health community are in agreement that the PMI must be a sustainable effort, so that the real question becomes, “What direction(s) can the PMI effectively take?”.

DEFINITIONS OF PRECISION MEDICINE AND PRECISION PUBLIC HEALTH

The definition of a particular medical intervention illustrates both the basic actions to be taken and its scope. Jameson and Longo define “precision medicine” as “treatments targeted to the needs of individual patients on the basis of genetic, biomarker, phenotypic, or psychosocial characteristics that distinguish a given patient from other patients with similar clinical presentations” [5]. Implicit in this definition is the goal of improving clinical outcomes for individual patients, while avoiding unnecessary side-effects that could be incurred by ignoring patients’ individual characteristics. The authors admit that medicine to date has more or less employed such an approach. Hemophilia requires the administration of an appropriate clotting factor, be it factor VIII or factor IX (these days in recombinant form), to stop the bleeding. Clinicians need to undertake a thorough work-up in order to arrive at a precise diagnosis of the hemophilia, which will enable the appropriate therapy to be administered. Choice of antibiotic is another example. For the antibiotic to take hold, the right type of antibiotic must be given for the particular bacterial infection. The latter example suggests that targeted approaches, aimed at particular persons for specific conditions, could actually have population-level applicability, since antibiotics and vaccinations are given on a widespread basis. They are the very opposite of “orphan drugs”, designed to cater to the needs of very rare cases.

Shen and Hwang point out that despite the commonality with past precedent, a substantive shift in methodology between the old medicine and the new medicine is occurring [6]. The practice of medicine has so far remained largely “empirical”. Physicians typically rely on a combination of patient and occasionally family medical history, physical examination, and laboratory data to secure a diagnosis and choose a drug. Treatments are

based on a provider's experience with similar patients. Drugs administered are most often "blockbuster" drugs designed to accommodate the "typical" patient. If the wrong analgesic, antibiotic, or antiarrhythmic is given, the patient will be weaned off the current drug, and a new one tested until the right drug and dosage are chosen. The idea behind precision medicine is to rely on new biomarkers and genomic tests to "deliver the right treatment to the right patient at the right time" [6]. It is a personally tailored, as opposed to "one size fits all" approach. The fit is "precise" – one person; one drug.

Classic pharmacogenomic examples readily demonstrate this novel approach. Warfarin (brand name Coumadin) dosing allows the frequently used anticoagulant to be titrated to the needs of the patient susceptible to clotting events associated with atrial fibrillation and deep vein thrombosis [7]. Two genes are known to be involved in warfarin therapeutic outcomes – *CYP2C9*, which codes for an enzyme primarily responsible for warfarin metabolism, and *VKORC1*, which codes for the warfarin drug target. Genotyping can yield information useful to guide a person's initial warfarin dose and allow the clinician to readily stabilize his or her prothrombin measures, a process which usually takes several weeks. Cost-effectiveness studies of genotype-guided dosing have concluded that considerable potential exists for cost savings, but that it cannot be realized until test costs decrease and the uncertainty concerning effectiveness is reduced. The U.S. Centers for Medicare and Medicaid Services (CMS) has consequently adopted a provisional "coverage with evidence development" approach [7]. A physiologic measure, the ratio of the patient's prothrombin time to a control or "normal" sample, continues to be the professional standard for warfarin dosing. Since the patient is followed with this measure, its use may be considered a tool in "personalized" or individually-tailored medicine.

Imatinib (Gleevec) for chronic myelogenous leukemia (CML) and gastrointestinal stromal tumors is another prime example of the tailoring in drug regimens that may take place. Medical researchers developed this drug over a multi-decade period to inhibit the function of a translocation-related "fusion" gene, *BCR-Abl*, which produces an abnormal tyrosine kinase that is not properly regulated [8]. In initial trials, all of 31 research participants experienced complete remission. The five year survival rate for CML has increased from 31% (1993) to 59% (2003 – 2009) [9]. The drug is administered to patients who are Ph⁺ (Philadelphia chromosome positive), with effectiveness monitored by white blood cell and platelet counts. Like warfarin, Gleevec targets a particular type of patient and has a very specific chemical target – the ATP-binding site on a particular kinase – and is a drug that can be closely monitored. Gleevec's cost is about \$3,500 per month, which may evade some patients' pocketbooks. However, it is covered by Medicare Part D and Medicare Advantage Plans. Both of the above examples describe "personalized medicine" – separating patients into different groups then individually tailoring the treatment to the patient.

Though many authors use the two terms interchangeably, Khoury distinguishes "personalized medicine" from "precision medicine" in that the latter inculcates multiple determinants of health, genetics being one rung, thus can absorb the notion of social determinants as easily as it can molecular determinants. The President's PMI plan is data intensive in a way that would allow the recording of multiple determinants for large numbers of people, ostensibly through a planned million-person cohort:

Participants will be involved in the design of the Initiative and will have the opportunity to contribute diverse sources of data – including medical records; profiles of the patient’s genes, metabolites (chemical makeup), and microorganisms in and on the body; environmental and lifestyle data; patient generated information; and personal device and sensor data. [1]

Collins and Varmus write that the numerous clinical trials stemming from the PMI and its large-scale cohort will require the building of a “cancer knowledge network” to store all the resulting molecular and medical data in digital form and make it readily deliverable to providers and patients [2]. Simonds and Khoury illustrate this idea with the example of a cancer clinical trials and effectiveness research infrastructure developed by the H. Lee Moffitt Cancer Center. The system is part of its personalized cancer care initiative started in 2006 – Total Cancer Care. The program: (1) integrates data from multiple sources (electronic medical records, biospecimen databases, and molecular data); (2) makes resultant information available to patients by providing active feedback about their health and upcoming appointments and expanded electronic health record; and (3) affords data interfaces for researchers and clinicians [10].

It is to be hoped that the streamlining of cancer clinical trials and centralization of incoming data will reduce costs and increase efficiency over standard medical practices. According to Cancer Research U.K., between 2003 and 2007 cancer trials were accompanied by a 75% increase in administrative costs, a figure in need of remedy [11]. Cost-effectiveness and clinical utility will enter into assessments of the PMI. Public health efforts in the U.S. have to date assumed a twin duty – assessment of the cost-effectiveness of clinical programs, at the same time that a vision of precision medicine’s meaning in terms of population health is being formulated. This vision departs from the medical model of precision health in a number of important respects: (1) it is population-based, with attention to at-risk populations, as opposed to being strictly individualized; (2) the focus is on primary and secondary prevention, rather than frank disease (tertiary prevention); and (3) the emphasis is on interventions that have already demonstrated readiness for large-scale implementation, in contrast to the undertaking of novel clinical trials [12]. To glimpse the future, it is helpful to visit recent experience with precision medicine in the cancer arena. This inspection will take our trek from the individually-focused domain of clinical medicine to the population-oriented territory of public health. The next section will focus on three major cancer categories of mutual interest to clinical medicine and public health – lung, breast, and colorectal cancer – from the medical pharmacogenomics point of view.

PHARMACOGENOMIC INTERVENTIONS AND COST-EFFECTIVENESS

The Precision Medicine Approach to Lung Cancer

Lung cancer is the second most common cancer in both men and women, and is the leading cause of cancer-related death in both genders [13, 14]. Of note, the lung cancer incidence rate for black women is roughly equal to that of white women, despite the fact that they smoke fewer cigarettes [13]. The two major forms of lung cancer are non-small cell lung cancer (NSCLC), and small cell lung cancer (SCLC). NSCLC comprises ~85% of all lung

cancers; SCLC ~10-15% [15]. The 5-year survival rate for NSCLC is 21%, suggesting progress that has been and that is yet to be made [16].

Targeted therapies aimed at cancers harboring very specific genetic alterations are becoming more and more common in oncogenomics. A 2012 review of the role of pharmacogenomics in moving genetic association studies from bench to bedside describes the use of EGFR tyrosine kinase inhibitors (TKI) in the treatment of lung cancer and *HER2* (tyrosine kinase ERBB2)-directed therapies in the treatment of *HER2* (human epidermal growth factor 2)-positive early-stage breast cancer as prime examples of success in the area of cancer pharmacogenomics [17]. A 2016 review of precision medicine approaches in oncology cites ALK (anaplastic lymphoma kinase) fusion oncogene and EGFR (epidermal growth factor receptor (EGFR)) mutations as the main molecular predictive biomarkers supporting NSCLC treatment [15]. Molecular testing for ALK fusion genes has proven valuable. Abbott Molecular already offers a multiplexed assay, the Vysis ALK Break Apart FISH Probe Kit, endorsed by the 2016 National Comprehensive Cancer Network (NCCN) NSCLC practice guidelines [15]. Though ALK fusion gene rearrangements are relatively rare (< 5% of NSCLC cases), clinical responses to targeted inhibitors (e.g., crizotinib) can be quite dramatic [5]. In favor of the precision medicine approach, excluding patients without these mutations can also minimize the exposure of patients to costly and potentially toxic therapies unlikely to benefit them.

EML4-ALK is the specific biomarker used in determining patient efficacy for the choice of a TKI agent such as crizotinib in the tertiary or after-the-cancer-has-arisen management of NSCLC [5]. A 2014 cost-effectiveness study on the use of *EML4-ALK* fusion oncogene testing in first-line crizotinib treatment for patients with advanced NSCLC reveals the complexity inherent in this precision medicine approach [18, 19]. The investigative team found that *EML4-ALK* testing to govern therapeutic decisions improved patient outcomes by an average of 0.011 quality-adjusted life-years (QALYs) while adding extra costs of \$2,725 per patient, of which only \$60 was attributable to the molecular assay itself. The overall interpretation of the cost-benefit calculus changes dramatically, however, when the cost of the companion drug (crizotinib) is considered. The incremental cost-effectiveness ratio is defined as the difference in cost between two alternative interventions, divided by the difference in their effect or impact. The incremental cost effectiveness ratio for administration of the drug itself was \$250,632 per QALY gained. The investigators concluded that the regimen is “likely not considered cost-effective in the current setting” [19]. This assessment was unaltered when the model was subjected to a sensitivity analysis of alternative costs for the molecular testing. States one reviewer, “Where companion diagnostic precision medicine is considered, these assays are by nature tightly coupled to the cost of the specific associated drug” [18].

Assays for EGFR inhibition may be used when other TKI inhibitors, such as gefitinib and osimertinib, are being considered for NSCLC therapy [15]. The U.S. Food and Drug Administration (FDA) has approved two multiplex assay kits, also NCCN endorsed, for this purpose – the *therascreen* EGFR RGQ PCR Kit (for use with gefitinib), and the cobas EGFR Mutation Test (for use with osimertinib). A cost-effectiveness analysis performed by an Australian team compared the use of combined multiplex testing and targeted therapy with NSCLC chemotherapy without testing, and thirdly with best supportive care without testing [20]. The combined strategy resulted in an additional 0.009 life-years (LYs) gained, compared to 1.458 LYs gained in the case of each of the other two strategies. The combined strategy resulted in an incremental cost-effectiveness ratio of \$485,199 (Australian)/QALY

comparing combined and best supportive care strategies, and \$489,338 (Australian)/QALY comparing combined and chemotherapy only strategies. Decreasing test and test interpretation costs by half reduced the ratios, but they still remained greater than \$200,000 (Australian)/QALY. The authors concluded that multiplex testing and targeted therapy is not cost-effective as a fourth-line treatment in metastatic lung cancer when first-line treatments such as chemotherapy without pharmacogenomics testing can be employed.

Other predictive biomarkers for NSCLC treatment are on the horizon. For example, *KRAS* mutations can suggest lack of therapeutic efficacy to EGFR targeted therapies. The FDA has cleared *KRAS* mutation detection assays for use in colorectal cancer, but such assays have not yet been approved for use in NSCLC [15].

The Precision Medicine Approach to Breast Cancer

Breast cancer is the most common cancer among American women. It is the second leading cause of cancer death in women, exceeded only by lung cancer [21]. About 85% of breast cancer cases occur in women with no family history of breast cancer. These cases are due to somatic cell mutations which occur as a result of aging, various exposures (such as pre- and postmenopausal hormone therapy), and other life events.

Precision medicine efforts for breast cancer due to somatic mutations fall into at least four categories, two of them – endocrine therapy and *HER2* therapy – being mainstay treatment categories. *HER2*-directed therapies, for which trastuzumab (Herceptin) is often used, are one of the two major pharmacogenomics successes in the cancer area cited by Ritchie [17]. Tamoxifen is a major drug of choice in the category of endocrine therapies, itself being a selective estrogen receptor modulator [15].

Herceptin has proven utility in reducing risk for cancer recurrence after surgery for early-stage *HER2*-positive (*HER2*+) breast cancer, and improving survival in late-stage (metastatic) *HER2*+ breast cancer, but it also poses serious side-effects such as heart damage. Herceptin therapy can also cost a sizable amount, up to \$50,000 per year [22]. Overexpression of the *HER2* gene (*HER2*+ status) is associated with rapid tumor growth and negative diagnostic and prognostic indicators. A systematic review and meta-analysis performed in Canada compared seven different strategies employing immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) to determine *HER2* status, thus appropriateness of using Herceptin [22]. Each strategy utilized an IHC score (0, 1+, 2+, 3+) alone or coupled with FISH confirmation to form this inference. The incremental cost-effectiveness ratio was lowest when cases with an IHC score of 2+ or 3+ (as opposed to 0 or 1+) were confirmed by FISH, which yielded a ratio of \$3,351 (Canadian)(minimum) to \$12,230 (Canadian) (maximum) per accurately determined case. The cost-effectiveness analysis is favorable given that accurate assessment of *HER2* status is capable of reducing the cost of Herceptin therapy by \$0.6 million per year, and saving \$12 million per year in women who are *HER2*-, thus can be kept off Herceptin [22].

Estrogen-focused therapies have been a part of standard care for more than thirty years, and have displayed an evolution in policy analysts' thoughts about the gold standard for precision management [15]. The Evaluation of Genomic Applications in Practice and Prevention (EGAPP) Working Group was launched by the CDC Office of Public Health

Genomics in 2004 to conduct systematic, evidence-based reviews of burgeoning genetic tests and other applications of genetic technologies in transition from research to clinical and public health practice. EGAPP has produced two systematic reviews of the use of gene expression profiling to improve therapeutic outcomes in women with breast cancer. EGAPP's 2009 review examined the validity and utility of three tests – Oncotype DX, MammaPrint, and the H:I (normalized gene expression) ratio [23]. These tests have been designed to go beyond the standard estrogen/progesterone receptor status indicator to predict tumor recurrence risk for women on tamoxifen, for whom alternative therapies might be considered. The EGAPP Working Group found adequate evidence from the NSABP B-14 randomized controlled trial to support the association between Oncotype DX recurrence scores and 10-year distant metastases in estrogen receptor positive (ER+) patients, and adequate evidence to support the association between RS score and overall chemotherapy benefit, particularly for patients in the high risk category [23]. Recent publication of interim results for the TAILORx study has shown a further association between recurrence score and 5-year disease-free survival and distant recurrence in patients at low risk [24].

A follow-up systematic review by the EGAPP Working Group published in 2016 confirmed its previous findings but also noted the lack of direct evidence that the use of Oncotype DX improves clinical outcomes [25]. It also highlighted contradictory cost-effectiveness results in studies performed in the U.S. (for which \$2,000 in cost savings per patient were due to a decrease in post-testing chemotherapy use) and the U.K. (for which an incremental cost-effectiveness ratio of 26,940 £/QALY gained were due to an increase in chemotherapy use) [25]. The U.K. National Institute for Health and Care Excellence (NICE) Diagnostics Advisory Committee concluded that, under the assumption of equal chemotherapy benefit for all Oncotype DX risk categories, the test is not cost-effective at its current pricing level. In the first EGAPP review, data were adequate to support an association between the MammaPrint Index and 5- to 10-year metastasis rates, but the efficacy relative to classical clinical factors was unclear. More conclusive results await the completion of the MINDACT trial. For the H:I ratio test, populations studied were quite heterogeneous, and the test's commercial offering was based on a single study in women with primary, untreated breast cancer.

The Precision Medicine Approach to Colorectal Cancer

Colorectal cancer (CRC) is the third most common cancer in both men and women in the U.S. [26]. It is the third leading cause of cancer deaths when men and women are considered separately, and the second leading cause in both sexes combined.

Considerable effort has been placed into targeted therapies and companion diagnostics for CRC. About 70-80% of patients present with resectable localized disease, treated by surgery and often followed by adjuvant therapy [27]. CRC patients with advanced disease may receive first-line chemotherapy, or chemotherapy and radiation before surgery is considered. The EGAPP Working Group published in 2009 a systematic review of one first-line chemotherapeutic agent, irinotecan, which may be accompanied by *UGT1A1* genotyping to check for ability to adequately clear the drug [27]. Such genotyping aids decisions to either increase drug dose for more aggressive therapy, or switch to common alternate drugs,

bevacizumab or cetuximab, for instance, in individuals with reduced clearance at risk for adverse events. EGAPP had two major findings: (1) unless patients receive a certain threshold dose of irinotecan, the increase in risk for toxicity is not significant, thus testing may not be warranted; and (2) reducing the dose of irinotecan (personalized dosing) to avoid adverse events may lead to more cases of unresponsive tumors than instances of adverse events avoided. It is inconclusive that benefits outweigh harms in the application of a precision approach here.

The alternate drugs mentioned above are positioned among the three main classes of targeted therapies approved for metastatic CRC: (1) multikinase inhibitors; (2) angiogenic inhibitors; and (3) anti-EGFR antibodies [15]. Up to 50% of CRC patients respond to anti-EGFR therapy, which includes cetuximab [28]. *KRAS* wild-type status is considered an important factor in achieving a clinical response from this category of therapy [29]. However, 40-60% of patients with wild-type status do not respond to such therapy. Data suggest that *BRAF* gene status also plays a role in anti-EGFR response, and that the *BRAF* V600E mutation, present in 5-10% of CRC tumors, can lead to a positive response. To date the FDA has cleared two genetic testing kits, the *therascreen* *KRAS* kit from Qiagen, and the cobas *KRAS* Mutation Test from Roche [15]. The American Society for Clinical Oncology (ASCO) and three other professional organizations released new consensus guidelines in 2015 strongly recommending *KRAS* mutational testing for patients being considered for anti-EGFR therapy, and that *BRAF* V600 testing also be considered.

Table 1. Pharmacogenomic/companion diagnostic approach – 3 cancers

Condition	Therapy	Biomarkers	Cost-Effectiveness	References
Non-small cell lung cancer (NSCLC)	Tyrosine kinase inhibitors	<i>EML4-ALK</i>	\$255,970/QALY gained	Djalalov et al. [19]
		EGFR	\$489,338 (Austr.)/QALY gained	Doble et al. [20]
HER2+ Breast cancer	Herceptin	IHC, FISH	\$3,351 – 12,230 (Can.) saved per case	Dendukuri et al. [22]
ER+ Breast cancer	Endocrine	21-gene assay	26,940 £ (Brit.) cost/QALY gained	EGAPP [25]; Ward et al. [33]
Metastatic colorectal cancer	Topoisomerase 1 inhibitor (TOP1) – irinotecan Anti-EGFR	<i>UGT1A1</i> genotyping	ambivalent results – reducing toxicity vs. reducing tumor burden	EGAPP [27]
		<i>KRAS</i>	\$7,500 – 12,400 saved per case \$180,000/QALY gained	EGAPP [30]; Vijayaraghavan et al. [31] EGAPP [30]; Shirowa et al. [32]

The EGAPP Working Group conducted a systematic review of companion diagnostic use of *KRAS* and *BRAF* mutation testing in anti-EGFR therapy in 2013 [30]. The systematic review looked at multiple pooled assessments, each consisting of up to seven studies, which together indicated statistically significant increased response rates to cetuximab and other anti-EGFR drugs, reduced risk of disease progression, and enhanced overall survival with *KRAS* wild-type status. EGAPP cited a cost-effectiveness study of *KRAS* testing in metastatic CRC patients in the U.S. and Germany [30, 31]. For the U.S. patients, use of *KRAS* testing to

select patients for EGFR inhibitor therapy saved \$7,500 to \$12,400 per case. A second cited study from Japan displayed an incremental cost-effectiveness ratio for cetuximab with *KRAS* testing to be \$180,000 per QALY gained compared to therapy without testing [32]. Due to this cost, the investigators concluded that the protocol was not cost-effective, even when treatment was limited to patients with wild-type *KRAS*. Two of three studies looking at *BRAF* testing found associations similar to the *KRAS* studies in terms of progression-free and overall survival, but these findings, however, were not contingent on whether or not cetuximab was included in the combination therapy. Thus, while the review supported recommendations for a precision approach using *KRAS* mutation testing, it found insufficient evidence to link *BRAF* V600E mutation testing with treatment response independent of prognostic association.

Table 1 summarizes the cost-effectiveness and descriptive findings for the pharmacogenomics or companion diagnostic precision medicine approach to the three cancers.

TAKING PRECISION MEDICINE BEYOND THE PERSONALIZED LEVEL

One argument against the informativeness of the above studies is that they represent a personalized medicine approach, but not a precision medicine approach in its full capacity [3]. The electronic storage of information, which can be multifactorial, including relevant lifestyle, would seem to be crucial to maximizing benefits and minimizing cost. The investigative team looking at the infrastructure characteristics of the Lee Moffit Cancer Center “Total Cancer Care” program also examined six other major healthcare programs engaged in cancer care comparative effectiveness research in genomic and precision medicine [10]. Four of the researched programs – at Duke University, Kaiser Permanente, University of Pennsylvania, and the Fred Hutchinson Cancer Center – had established a complex infrastructure (with data and biospecimen registries and multidisciplinary research teams), were engaged in “knowledge generation” (via randomized controlled trials and observational studies), and had reached the stage of “knowledge synthesis” (horizon scanning, evidence synthesis, and decision modeling). These programs display a depth of information and range of multidisciplinary expertise that is reflective of the type of knowledge synthesis of which the PMI’s million person cohort will be capable.

The Duke University and Kaiser Permanente teams noted a number of strategic challenges to the amassing of cancer study data – limited data quality, large variation in genomic methodology used, and poor demonstration of clinical utility for the genomic tests supplying the data [10]. These observations point out challenges that could foreseeably face PMI investigators attempting to collate information from the expansive precision medicine cohort. The Kaiser Permanente group was able to show that in screening for Lynch syndrome, a hereditary form of CRC, microsatellite instability testing (MSI) was preferable compared to immunohistochemical staining (IHC). In the treatment phase, the investigators found that screening for *KRAS* and *BRAF* mutations improved the cost-effectiveness of anti-EGFR therapy, but that the cost of the therapy surpassed generally accepted cost-effectiveness thresholds of \$100,000/quality-adjusted life-year. These findings allude to the capability of the PMI to develop new data on useful oncogenomic screening, mutational testing, and therapeutic procedures, and to the correspondingly likely possibility that many of the

discoveries, while being individually beneficial, could elude effectiveness for the clinical population as a whole.

The PMI will no doubt be carried in new directions that have not yet been quantified, however. NCI is engaged a new type of clinical trial called “NCI-MATCH” [34]. In this innovative program, adult cancer patients are assigned to targeted treatments based on the genetic abnormalities in their tumors, regardless of the type of cancer they have. This concept represents the therapeutic end of what has been happening with diagnostics. *KRAS* and *EGFR* mutation testing is now occurring for multiple cancer types. Why should cancer therapies be restricted to just one cancer type? New management models may also evolve. The data infrastructure supporting precision medicine can and is being used to develop procedural algorithms that combine genetic testing with genetically targeted therapies. These algorithms, if tailored to the lay person, can then be used by both medical providers and patients in collaboration, improving the effectiveness of the prescribed regimen. Shen and Hwang use *CYP2C9* (they cite *CYP450*) testing for warfarin dose performed at home first by nurses then by patients as an example [6]. This linkage of “big” or “rich” data and the development of new, useful algorithms is cited by multiple authors [2, 5, 35]. The issue is whether providers of various types, and consumers, can understand the test results and appreciate the connection to one-size-does-not-fit-all therapeutic management [36].

Authors discussing the translation of big data into usable guidelines and algorithms are not just limiting the payoff to individualized treatment, however. Jameson and Longo, for instance, speak of not just a pharmacogenomic future, but one in which “guideline-based screening”, e.g., colonoscopy, can be targeted on the basis of age and family history [5]. Family health history is one of several tools, including individualized genetic testing and family cascade testing, fueling the public health drive towards precision interventions [37, 38].

The public health approach to precision medicine, or “precision public health”, is highly evidence-based. Precision public health is exemplified in the Centers for Disease Control and Prevention’s emphasis on the implementation of Tier 1 genetic tests that have passed systematic review for analytic and clinical validity and utility – family history-based hereditary breast and ovarian cancer (HBOC) genetic testing (*BRCA1/2* mutations in relatives), and hereditary nonpolyposis colorectal cancer genetic testing (Lynch syndrome *MLH1*, *MSH2*, *MSH6*, *PMS2*, *EPCAM* mutations) [39]. Indeed, genetic counseling and testing for HBOC are already incorporated into healthcare reform as services not requiring co-pay for individuals deemed at risk by their providers [40]. The PMI promises much more, however, and part of the vision of public health is that precision techniques can be used to direct genetic preventive strategies to those subsets of the population that will derive maximal benefit [41].

PUBLIC HEALTH INTERVENTIONS AND COST-EFFECTIVENESS

The Precision Public Health Approach to Lung Cancer

It has been remarked that “although personalized treatments can help save the lives of sick people, prevention applies to all” [3]. This comment applies especially to lung cancer,

which can be tackled as we have seen individually and after it has manifested, or by using a preventive, population-based approach. Initial genome-wide association studies (GWAS) published by several investigative teams in 2008 were suggestive of lung cancer susceptibility genes being situated on the long arm of chromosome 15 [42]. The studies were all large (3,500 to 14,000 participants) and replicated, yielding strong evidence for an association between SNP variations at 15q24/15q25.1 and lung cancer. Thorgeirsson et al. found a highly significant association ($P = 1.5 \times 10^{-8}$) between a common variant in the nicotinic acetylcholine receptor gene cluster on chromosome 15q24 and smoking frequency, with an odds ratio of 1.31 (1.19 – 1.44, 95% C.I.) between nicotine dependent cases and low quantity smokers plus population controls [43]. Studies by Hung et al. [44] and Amos et al. [45] found odds ratios between 1.21 and 1.77 for associations between the nicotinic acetylcholine receptor regions 15q25 and 15q25.1 and lung cancer in ever smokers, the former accounting for 14% (attributable risk) of the lung cancer cases in the first study. The second study examined 2,724 NSCLC cases, the same type of cancer being treated in later stages by pharmacogenomics regimens.

More recent GWAS in never-smoking Asian females have pointed out genetic associations independent of smoking status. Case-control studies of never-smoking Asian females funded through the National Institutes of Health [46] and the Mayo Foundation [47] have identified genetic variants in the 3q28 and 13q31.3 regions associated with risk for lung cancer ($N = 754$ to 7,254 participants). These associations show both statistical significance ($P = 10^{-6}$ to 10^{-8}) in terms of odds ratios and allelic risk, and biological plausibility (association with the regulation of cell proliferation and division). These two lines of discovery – lung cancer in connection with nicotine dependence and independent of it – could beneficially lead to both personalized smoking-cessation interventions, and to increased screening of people at risk for lung cancer [41]. The difficulty is that the association studies are at the primary research (T1) stage and do not yet imply clinical validity.

Precision medicine in public health terms involves targeting groups at risk. Various professional societies have developed guidelines for lung cancer screening, generally beginning at age 55 [48]. The NCCN lung cancer screening guidelines recommend screening individuals age 50-55 years, those who have between 20 and 30 pack-years of exposure, and who exhibit one additional risk factor, such as family history. The relative risk of developing lung cancer is 1.8 if the individual has at least one first-degree relative with lung cancer, and 3.0 given two first-degree relatives with the condition [49]. The positive and negative predictive values for lung cancer appearing in a proband's first-degree relatives are 89.9% and 99.1%, respectively [50]. In the Utah Family High Risk Program, the cost of taking a family health history varied between \$10 and \$25 depending upon receipt of follow-up educational interventions [51]. These figures indicate cost-effectiveness for the use of family history in risk assessment for lung cancer.

Public health programs are especially concerned with the rights and welfare of underserved groups, an aim that is built into public health codes of ethics [52]. Surprisingly, of the 58,160 lung disease studies published between 1993 and 2013, less than 5% reported the inclusion of minority participants [53]. NIH is presently consulting researchers adept at recruiting under-represented groups into studies as part of PMI Research Cohort formation. An admixture study of 1812 African Americans performed by the Karmanos Cancer Institute in Detroit, MI demonstrates what can come out of the use of the PMI Cohort. Excess African

ancestry was observed on chromosome 3q among ever smokers with NSCLC, a chromosomal region identified by previous studies with mostly persons of European ancestry [54].

The Precision Public Health Approach to Breast Cancer

About 10 to 15% of women diagnosed with breast cancer have germline mutations in the *BRCA1* or *2* genes. Between 10 and 30% of women under age 60 diagnosed with triple-negative breast cancer (cancer which does not have receptors for estrogen, progesterone, or *HER2/neu*) display a *BRCA1/2* mutation [55]. Ashkenazi Jewish ancestry confers an increased risk, though such mutations are by no means relegated to just one group. Like lung cancer, the public health approach to hereditary breast and ovarian cancer (HBOC) focuses on primary prevention before disease has appeared. Primary prevention can be conducted through a variety of means, several of which fit under a public health precision model. A study out of the Cleveland Clinic Genomic Medicine Institute compared two methods for cancer risk assessment – “family history-based risk assessment” and “DTC [Direct-to-Consumer] personal genomic screening,” the latter using a variety of risk alleles [56]. Of 22 high risk females appearing in clinic, family history classified eight individuals as being at risk for breast cancer, but only one of the eight was classified as high-risk through personal genomic screening method.

Family history is a quick way of identifying risk, and has value in this instance as it does with lung cancer. Valdez et al. note that the relative risk of developing breast cancer is 1.8 and ovarian cancer 2.9 if the individual has at least one first-degree relative with these conditions [49]. It is 3.0 and 14.7 given two affected first-degree relatives. The positive and negative predictive values for these cancers appearing in a proband’s first-degree relatives are 89.1% and 98.9% for breast cancer, and 76.1% and 99.3% for ovarian cancer [50]. The U.S. Preventive Services Task Force (USPSTF) has conducted evidence reviews of genetic testing for the key mutations involved in HBOC, *BRCA1* and *2*. It recommends:

Primary care providers screen women who have family members with breast, ovarian, tubal, or peritoneal cancer with 1 of several screening tools designed to identify a family history that may be associated with an increased risk for potentially harmful mutations in breast cancer susceptibility genes (*BRCA1* or *BRCA2*). Women with positive screening results should receive genetic counseling and, if indicated after counseling, *BRCA* testing. [57]

The CDC-OPHG classifies the use of family history of known breast/ovarian cancer with deleterious *BRCA* mutations as Tier 1 [39]. CDC defines Tier 1 genetic interventions as those supported by clinical practice guidelines based on thorough systematic review. These modalities are ready for implementation not just on the individual but on the level of the at-risk population as well [38].

Family history, however, is part of a train of diagnostic interventions, including genetic counseling and genetic testing. The latter can lead to annual screening via MRI or to surgery. A 2012 cost-effectiveness analysis of *BRCA1/2* testing of women ≥ 35 years at elevated risk of carrying a mutation, considering the eventual use of these MRI and surgery, determined genetic testing to be cost-effective if testing cost were $\leq \$8,948$ [58]. Currently targeted *BRCA1/2* mutation testing ranges from \$4,500 to \$650 [58, 59].

Economies of scale operate when identifying persons at risk for cancer. Identifying single individuals can be expected to be less efficient than pinpointing families at risk, just as using information reflecting population risk data can be expected to be more efficient than utilizing separate family histories. Cascade screening is the testing of successive test positive family members starting with a positive index case. Two studies delineate that the success of *BRCA1/2* cascade screening in affected families, as measured by actual uptake of genetic testing, is a function of ability of family members to communicate with one another, and to attend a clinical session [60, 61]. Uptake rates of 54% (Utah study) and 73% (Manchester portion of U.K. study) were achieved when these conditions were satisfied. The London portion of the U.K. study, which covered a more dispersed population, achieved 62% for those clinically seen. George et al. indicate that the cost of *BRCA* testing in 30 at-risk relatives can be brought down from a minimum of \$66,000 to \$12,000 once the responsible mutation has been identified in a family member [62].

On a population level, it is possible to gather information on early-stage breast and ovarian cancer, and to report aggregate information back to participating institutions. A breast cancer incidence study utilizing the Connecticut Tumor Registry found that the ability to detect cases depends on the relative population size of the groups being assessed (here white versus nonwhite) [63]. Population-based risk assessment has the advantage of detecting *BRCA1/2* carriers with a negative family history. Clinical validity goes up with the prevalence of a disorder in a given population. Rubinstein et al. performed a decision analysis of *BRCA1/2* testing in American Ashkenazi Jewish women aged 35-55 years [64]. At a cost of \$460 for founder mutation testing, the investigators concluded that such a program is cost-effective, amounting to \$8,300/QALY gained.

The PMI, like state cancer registries, is especially geared towards targeting at-risk individuals and populations. The CDC notes that state health departments have engaged in bidirectional reporting, i.e., identification of cases from the state tumor registry, and reporting back of information to participating facilities. The Michigan Department of Health and Human Services and Connecticut Department of Health have both identified thousands of cases of breast and ovarian cancer suggesting risk for HBOC, and returned back facility-specific data [65]. In the case of Connecticut, facility-specific reports on numbers of breast and ovarian cancers, compiled from 3,792 cases in the state cancer registry, were reported back to providers to alert them that patients might be at an increased risk for HBOC. Staff at 70% of the 32 involved hospitals also requested and received an HBOC training session.

In the age of electronic health records (EHRs), systems can be designed to provide physicians with decision support tools that alert them to the need for genetic testing, and assist with interpretation of results and potential impact on patients and their families [11]. It is also possible with EHR systems to flag patients who are members of high-risk families to make them aware of their risk status and available options [66, 67].

The Precision Public Health Approach to Colorectal Cancer

The hereditary form of CRC that has received the most public health and medical attention is hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome (LS), which produces only a small number of polyps or none at all. LS is the most common

heritable cause of CRC, representing 1 in 35 cases [66]. Whereas the lifetime risk for developing CRC is 2 to 5% in the general population, it is 80% in those with LS.

Family history as an instrument for performing cancer risk assessment in first- and second-degree relatives is even more accurate for CRC than for the other two families of cancers. Valdez et al. report that the relative risk for CRC is 2.2 given a first-degree relative with the condition, and 4.0 given at least two first-degree relatives with CRC [49]. Lynch syndrome is notoriously underdiagnosed, however. The vast majority of families with a history of CRC do not know they may have LS, or even that a genetic test is available [66]. Nevertheless, the EGAPP Working Group, using a chain of evidence methodology comparing four preliminary testing (MSI, IHC, and *BRAF*) and mismatch repair (MMR) gene strategies leading to medical and surgical management, found that adequate evidence exists that an appropriate testing strategy can improve clinical outcomes for patients and their families [68].

A precision public health approach to Lynch syndrome entails spotting cases before the management is made more complex by disease advancement, coupled with identifying at-risk relatives free of disease. A 2014 consensus statement by the U.S. Multi-Society Task Force on Colorectal Cancer looked at initial approaches for index case identification. Use of clinical criteria (e.g., the Revised Bethesda Guidelines) and a CRC risk assessment tool using family history – “selective approaches” used to identify a range of patients – both showed adequate sensitivity in identifying individuals with germline mutations, but up to 28% of LS patients can be missed with a liberal interpretation of the revised guidelines [69]. A more “universal approach” assessing LS risk based on IHC testing of all incoming cases of CRC was found to have greater sensitivity than selective strategies including the use of the Bethesda guidelines. Such an approach is still shy of being considered population-wide risk assessment in that testing begins with confirmed colorectal cancer cases. Multiple studies have shown that: (1) the systematic application of testing among patients with newly diagnosed CRC could provide substantial clinical benefits at acceptable costs; and (2) adopting a “universal” approach towards CRC genetic testing is cost-effective [69]. Palomaki et al., for example, found that a strategy employing IHC and *BRAF* preliminary testing followed by MMR mutation testing in *BRAF* negative cases would cost an average of \$18,863 per LS case detected [70].

Having identified an index case, the public health approach is then to move on to relatives to identify those at risk for LS, and those who are not. The EGAPP Working Group cites seven studies showing how uptake of colonoscopy by relatives with LS ranged from 53 to 100% [68]. Sharaf et al., in a sub-analysis of four select articles from a broader LS studies review, concluded that 52% or less of the first-degree relatives received LS genetic testing [71]. This number was critiqued by Jasperson, who noted that the Sharaf analysis excluded a large study containing 466 family members composed almost exclusively of first-degree relatives at high-risk of developing LS [72]. The latter study found 75% of the members to have been tested for LS mutations.

The cost of cascade testing is also a consideration. The per mutation cost of MMR gene testing for LS can decrease from \$1,000 to \$350 once a specific familial mutation has been identified in the proband [59]. The consequence is that the cost per LS index case can decrease from \$18,863 to \$13,000 [68]. In the most comprehensive cost-effectiveness assessment of universal and “near-universal” genetic screening to date, covering seven LS studies that also looked at medical/surgical follow-up and testing of relatives, Grosse found

that all except one reported incremental cost-effectiveness ratios less than the threshold \$100,000 per life-year or quality-adjusted life-year gained [73].

Table 2. Public health precision approach – 3 cancers

Condition	Genetic test	Cost-effectiveness	References
Familial lung cancer	Family history (FH)	*FP rate: 1.9 (female) – 6.1 (male) FN rate: 29.1 (female) – 37.5 (male) **PPV: 81.0 (68.6 – 90.1)*** NPV: 97.1 (96.0 – 98.0) Cost \$10 – 25/FH taken	Ziogas and Anton-Culver [50] Johnson et al. [51]
	GWAS – remains investigational		
Hereditary breast and ovarian cancer (HBOC)	<i>BRCA1/2</i>	Cost-effectiveness threshold \$8,948 (current testing \$650 – 4,500) \$8,300/QALY gained (U.S. Ashkenazi population)	Goodman [58] Rubinstein et al. [64]
Hereditary nonpolyposis colorectal cancer (Lynch syndrome – LS)	Multi-gene testing (<i>MLH1</i> , <i>MSH2</i> , <i>MSH6</i> , <i>PMS2</i> , <i>EPCAM</i>)	\$18,863 cost/index case \$13,000 cost/relative \$29,600 – 63,900/QALY gained (“universal” testing)	EGAPP [68]; Palomaki et al. [70] Grosse [73]

* False positive (FP) and false negative (FN) rates.

** Positive predictive value (PPV) and negative predictive value (NPV).

*** 95% Confidence interval.

As with HBOC, collection and reporting of LS data has occurred at the state level. Michigan identified 10,000 CRC cases from its cancer registry, and returned facility-specific data and educational materials to 145 reporting institutions [74]. Connecticut reported back information on 3,517 CRC cases in its cancer registry to targeted practitioners at acute care hospitals. These bidirectional reporting efforts show that health-related information may be stored *en masse* for both practical and research purposes (as in the PMI Cohort), and can be reissued for clinical and public health purposes.

The Colorado Department of Public Health and Environment also targeted educational outreach relating to hereditary CRC to 430 medical providers and 200 at-risk cases [74]. A survey was conducted which showed that 98% of provider and patient respondents thought that the information was clear and useful, many patients having indicated they engaged in further dialogue with their physician, a genetic counselor, or a family member. About 1/3 of the patient respondents communicated that they planned to have a risk assessment as a result of receiving the materials. The Colorado educational efforts were conducted by mail. An extensive, 33-study article review by Naylor et al. found that further patient education involving phone or in-person contact combined with patient navigation of resources can lead to improvements on the order of 15% in colorectal screening rates in minority populations [75].

Table 2 outlines the array of precision public health efforts, which involves targeting of screening, genetic testing, and education for the three cancer conditions.

CONCLUSION: CONTINUITY AND EMERGENCE IN PRECISION HEALTH APPROACHES

A major point brought out by the two tables is that pharmacogenomic regimens cost considerably more than primary prevention approaches to cancer management. From the articles reviewed herein, the former often exceed cost-effectiveness thresholds, though this conclusion need not necessarily be true for the regimens that are being offered. The cancer drug being prescribed is typically the main contributor to the cost, as opposed to the companion diagnostic, which can actually bring the price down. One can then view this conclusion in three ways: (1) optimistically, economies of scale or institutional policy changes might ultimately bring the cost of the pharmacogenomic regimen down; (2) the value of a person's life is to be held paramount, thus the costs incurred, from a private perspective, are worth it; or (3) the value of the primary prevention approach, due to its cost-effectiveness, is to be emphasized.

The medical and public health approaches are not to be viewed as mutually exclusive. Their territories are more like the circles of a Venn diagram which intersect with plenty of shared space in the middle. Both the CDC and its EGAPP program have devoted considerable attention to companion diagnostics and the attempt to prove that they have overall utility, including cost-effectiveness. Public health has an evaluative role that dips into hospital-based interventions. The national view is more one of mergence [3]. The fact that *BRCA1/2* genetic testing takes off where chemotherapeutic approaches to breast cancer leave off, in terms of the host cancer's hormone receptor status, indicates that the domains of the primary/secondary and tertiary prevention camps are complementary. It would be idealistic to assume that predictive genetic testing plus monitoring could eliminate all tumors before they spread. Both ends of the prevention continuum are needed, and the more targeted they are, the better. It is also important to recognize that the medical and public health approaches both defy stereotyping. The use of *KRAS* testing in anti-EGFR therapy of metastatic colorectal cancer can be cost-saving. The value of a public health approach genetic to lung cancer is limited by the current state of GWAS findings and the heavy influence of gene-environment interactions in the genesis of lung cancer. Indeed, some would argue that federal and state policy approaches towards smoking and lung cancer should take center stage.

Policymakers have a role in deciding allocation of healthcare dollars. In providing arguments for and against utility in this paper, we are not advocating a withdrawal of dollars from either medical or public health oncogenomic approaches. The case has been made for a more detailed consideration of the proportion of dollars that go towards prevention, however. The paper has not dealt just with chemotherapy, or just with Tier 1 genetic testing, however – emphasis has been placed on a precision approach for both. In public health, this nuance translates into tailoring the intervention towards communities at-risk or in-need. It will be more cost-effective thereby, and will achieve the ethical standard of addressing the health of all by attending to those most in need.

A final point should be made about the medical and public health precision approaches that are emerging. The medical approach is showing healthy signs of growth. The PMI Research Cohort will grant it the ability to host more clinical trials with suitable cohorts of participants, and to speed up the process of conducting clinical trials. As NCI plans, some of these trials will cross typological borders and target treatments based on somatic abnormalities in the tumors regardless of cancer type [34]. Public health research will also benefit from the PMI Cohort, especially in instances where major germline mutations have not turned up and GWAS are actively identifying lower risk alleles having a cumulative effect. Given the thought being given to participating groups, the discovery of new risk alleles will most certainly benefit diverse communities. The promise of tapping into lifestyle and environmental factors as data on the cohort participants builds will strengthen prevention approaches even further. The word “precision” also applies to the educational component of health programs. Educational efforts can become more tailored to the needs of at-risk groups as the data accumulates. Precision public health does not end with the target molecule, but with the whole person and the community to which he or she belongs.

Chapter 525

YOUTH GUN VIOLENCE: A GROWING PUBLIC HEALTH CONCERN

Amy Burnett*, MSN, APRN

Division of Adolescent Medicine and Young Parent programs,
J422 Kentucky Clinic, Department of Pediatrics,
Kentucky Children's Hospital, University of Kentucky College of Medicine,
Lexington, Kentucky, USA

ABSTRACT

Youth gun violence is a significant public health concern around the world. There have not been any certain methods or programs implemented that have been shown to significantly decrease this issue. There are some thoughts as to what would be effective interventions, but lack of research prevents evidence-based interventions from being implemented. Without addressing gun violence in the adolescent population, there will continue to be a disproportionate level of morbidity and mortality in our youth.

INTRODUCTION

Gun violence is a pervasive problem in today's society. It is difficult to watch the news without hearing of serious acts of harm toward individuals, with guns most commonly being the weapon of choice. The United States has a disproportionately high problem compared to most other developed countries, but there are growing issues around the globe. This form of violence is very frustrating for all sides involved due to the complexity of the problem. There seem to be many opinions on how to address this significant concern, but no effective solutions have been identified.

The thought as to why gun violence is more prevalent in the United States is largely due to social attitudes surrounding firearms and the ease of access. Guns are entrenched in the

* Corresponding Author's Email: amy.burnett1@uky.edu.

American culture [1]. There is an extremely strong gun lobby in the United States and firearm laws are more lenient than most other countries in the world. It is currently estimated that there are over 300 million guns in circulation in the United States, which is over three times as many as the 79 million throughout the European Union [2].

Overall, gun violence rates are down significantly since the peak in the 1990s [3]. Even with the decline in overall violence rates, youth gun violence prevalence remains somewhat alarming at this time. Worldwide, an average of 200,000 adolescents die from gun violence each year [4]. Unintentional injury remains the leading cause of death in adolescents in the United States, followed by suicide and homicide [5]. Homicide is the leading cause of death in African American males ages 10 to 24 years [6]. There are roughly three times the number of non-fatal injuries due to gun violence each year, which lead to significant physical, psychological, social, and financial burden to the individuals and families involved [4]. Youth homicides and assault-related injuries cost the United States alone about \$18 billion annually [6].

Not all gun violence is the same. There are two very distinct classifications of youth gun violence, which are mass shootings and street violence [7]. The characteristics of the perpetrator and their overall intent are generally very different between these groups. School shooters are statistically Caucasian males, little or no history of behavior problems, and have average to above average intelligence [7]. Many times the reason for mass/school shootings remains unknown. Street violence offenders, on the other hand, are statistically minorities from urban areas high in poverty and crime [7]. These shootings typically involve drugs, gang affiliation, neighborhood “turf” battles, and personal conflict [7]. Mass shooters will often commit suicide at the end of their rampage, but street shooters rarely do [8].

In most countries, there are laws prohibiting the legal purchase of firearms by a minor. This does not seem to stop adolescents from obtaining, carrying, and using guns. Many wonder about the ease of access and the availability of guns to this population. Mass shooters often purchase a gun legally, if over the legal age, or will obtain guns from within their homes [7]. It is estimated that 44% of homes in the United States have at least one gun [5]. Street shooters typically obtain guns from purchasing illegally on the street, taking guns from their homes, or stealing the firearms [7]. These individuals often feel the need to protect themselves and will carry guns on a regular basis [1].

It is important to be able to identify those youth that are at risk for gun violence. Statistically, males are the large majority of perpetrators of gun violence [9]. It is a common misconception that those with mental illness are at higher risk for gun violence, but actually only 4% of violent acts are committed by those with diagnosed severe mental illness [10]. Victims of bullying have been found to be at an increased risk of weapon carrying [11]. Exposure to violence in the home seems to be a large predictor of becoming a perpetrator of violence due to the physical and emotional trauma that children face [1]. One of the best predictors of violence in an individual is a history of past violent behavior [7].

PREVENTION AND INTERVENTION

One of the most difficult problems with regards to youth gun violence is prevention and intervention. There are many programs and efforts that have been initiated with varying levels

of success. The majority of these initiatives have been tailored to a certain population or geographic area to meet specific needs. There does not seem to be one strategy that is most effective and can be applied broadly. There are things that can be done by parents, school officials, the community, and medical providers that can help decrease the rates of violence in today's youth.

Parents have a large responsibility in gun violence prevention and intervention with their kids. It is essential that parents lock all guns that are inside the home to prevent easy access [9]. Parents should monitor their children closely and should know the social circles in which they belong, the places that they are going, and their exposure to violent media [1]. It is beneficial if parents are involved, supportive, and nurturing from a very early age and if they respond quickly and proactively to any signs of aggression that their child exhibits [7]. Dealing with stress and conflict in a positive way needs to be modeled by parents in the home in order to teach children the best way to react in these situations [1].

School officials have a large responsibility to monitor kids closely in the school setting in order to help identify those kids at risk for violence, but also to provide resources to parents and students about violence and potential interventions. Bullying must be monitored and handled appropriately in order to prevent those victims from acting on their frustrations [11]. School officials should foster a sense of safety for all children attending their school [1]. Any individuals that present with threatening behavior should be addressed immediately by school officials, school law enforcement, and mental health providers in order to assess the situation appropriately and identify the resources that can be used to resolve the concern. In-school violence prevention programs need to be initiated and strongly supported in order for a positive difference to be made [9].

The community has a strong influence on the actions of the individuals living there, especially the youth. There are areas, especially urban areas of high poverty, where violence is accepted as the norm and the community tolerates this behavior. It is up to community leaders and residents to change that way of thinking and the beliefs of their area, which is extremely difficult to do in most cases, in order for positive change to occur [12]. Community policing, which is where police are embedded in communities in order to form relationships and know the routines of an area, has been shown to be a positive influence on the individual satisfaction of residents and the community's trust in police. However, studies regarding community policing show no great decrease in overall crime rates due to these programs [13]. A community deterrence strategy, called pulling levers, has been shown to be successful in crime reduction. These pulling levers campaigns target individuals or areas in need and increase the social services and community resources, police activity, and frequency of communication with known violent offenders in efforts to help reduce crime rates [14]. Even though these interventions sound promising and show positive results, there is rarely sustainable funding to make these interventions a long-term solution.

Health care providers play a unique role in gun violence prevention. Since 1999, the American Academy of Pediatrics has endorsed routine screening of violence and gun safety in the child and adolescent population, but the actual number of providers performing these routine screens remains low [15]. Literature reviews show that performing routine screenings in the primary care setting can help lower overall violence rates. There are many screening tools available for various patient settings. By identifying those at risk through routine screenings, social and mental health resources can be made available to the patient in order to help prevent future violence or victimization. It is essential to provide therapy to those kids

exposed to gun violence, whether in the home or in the social setting [1]. Mental health treatment may be one of the best interventions that we have to offer in the outpatient setting at this time [9]. There have been numerous inpatient programs developed for identification and intervention on the inpatient side of care. Typically, patients are entered into these programs after being admitted to the hospital as a victim of gun violence. These programs provide different interventions while a victim is inpatient and some also have outpatient follow up. Inpatient violence prevention programs typically do show some benefit, but the programs need to be long-term in nature in order to significantly lower violent crime [16].

Due to the complexities of the gun violence problem at this time, more research is needed to explore various factors surrounding the issue in order to create better strategies for violence reduction. In the US, gun violence research has been controversial over the past two decades. In 1996, researchers at the Centers for Disease Control and Prevention (CDC) were banned from performing gun related research, which was thought to be due to the power of the American gun lobby and their influence on lawmakers [17]. By looking into certain aspects of gun violence, such as gun laws, media violence, and family and school influences, the problem could be understood better and there could be research focused interventions to help reduce youth gun violence [7].

CONCLUSION

In conclusion, youth gun violence is a serious public health concern in today's society. This issue is affecting all parts of the globe and little is being done to help resolve the problem. To decrease the rates of gun violence among youth, it will take a collaborative effort from parents, school officials, community members, and health care providers. With better research performed on the topic, these key players would be better equipped to develop effective prevention and intervention programs. It is hoped that there will be new understanding in the near future and the rates of youth gun violence will begin to decline.

HOW COMPUTER MODELS CAN DISTORT BAYESIAN UNCERTAINTY ABOUT PUBLIC-HEALTH HARM: SCIENTIFIC AND ETHICAL PROBLEMS

Kristin Shrader-Frechette

Department of Philosophy and Department of Biological Sciences,
University of Notre Dame, Notre Dame, Indiana, USA

Mathematics is, I believe, the chief source of the belief in eternal and exact truth as well as a sensible intelligent world.

Bertrand Russell

ABSTRACT

One of the major ways that scientists err in information-technology fields is by misusing quantitative risk assessments (QRAs) that employ flawed computer models. These computer models err because they characterize Bayesian situations of deep *uncertainty* (for which no reliable probabilities or frequency data are available) instead as situation of reliable, confirmed *risk* (for which reliable probabilities and frequency data are available). Mischaracterizing uncertainty as risk, scientists often claim low risks for breaching million-year nuclear-waste repositories, for the groundwater transmission of hazardous wastes, or for the thousand-year vulnerability of chemical facilities to terrorist attack. This chapter (1) outlines several scientific and ethical problems associated with using QRA computer models to mischaracterize potentially harmful, million-year situations of deep *uncertainty* instead as situations of *risk*. It shows that these public-health-related computer models typically (1.1) fail to do uncertainty analysis and (1.2) misrepresent the scientific nature of both prediction and uncertainty analysis. To show (1.1-1.2), the chapter (2) gives several prominent, current, scientific examples of these mischaracterizations that also threaten human welfare, namely, MIT's 1975 Reactor Safety Study; TRW's year-2000 Yucca Mountain environmental impact assessment; and the US Department of Energy's 2010 West Valley, NY environmental impact assessment. Finally, the chapter (3) reveals several practical ways to avoid such flawed computer modeling that also threatens public health and safety.

Keywords: MIT, nuclear reactor, prediction, quantitative risk assessment, subjective probability, uncertainty analysis, waste repository, West Valley, Yucca Mountain

INTRODUCTION

Henry Ford, the founder of the auto company and the developer of the assembly line, said that “Whether you think you can do it or not, you’re usually right.” Confidence alone may not generate success, but it’s usually necessary. Yet, from driving a car, to solving math problems, most people – including scientists – are more certain of their abilities and estimates than they deserve to be. Moreover, men are more over-confident than women are. When different scientists have equal ability and perform equally well on the same scientific questions, virtually all are overconfident, but women are 22 percent less so than men are (Kay and Shipman 2014).

Despite the value of confidence, overconfidence in science and engineering can lead to both error and catastrophe. This chapter shows that even prominent computer modelers have often been overconfident about their health-and-safety-related results, particularly in situations in which they either have no empirical data, or fail to use these data, to check their predictions.

OVERVIEW

The chapter reveals that a major source of scientific error in information-technology fields involves misuse of quantitative risk assessments (QRAs) that employ flawed computer models. These computer models err because they characterize Bayesian situations of deep *uncertainty* (for which no reliable probabilities or frequency data are available) instead as situation of reliable, confirmed *risk* (for which reliable probabilities and frequency data are available). Mischaracterizing uncertainty as risk, scientists often claim low risks for breaching million-year nuclear-waste repositories, for the groundwater transmission of hazardous wastes, or for the thousand-year vulnerability of chemical facilities to terrorist attack. The chapter (1) summarizes the difference between Bayesian risk and uncertainty, (2) gives three examples showing how prominent scientists and engineers misuse QRAs that employ flawed computer models, (3) outlines key scientific and ethical problems associated with using QRA computer models to mischaracterize potentially harmful, million-year situations of deep *uncertainty* instead as situations of *risk*, and (4) offers several practical ways to avoid these uncertainty-related scientific biases that result in massive threats to human welfare.

BAYESIAN UNCERTAINTY, RISK, AND MISREPRESENTATIONS OF UNCERTAINTY

Researchers and computer modelers doing welfare-related science frequently mischaracterize situations of Bayesian uncertainty and risk. Scientists who assess

technological risk, through techniques such as QRA, typically define risk as the annual probability that some damaging effect will occur, an effect such as a nuclear-reactor core melt or an effect such as a leak from a hazardous-waste facility. If scientists are overconfident about their computer-modeled risks, often they claim more reliability for their risk predictions and probabilities than is defensible. After all, scientists do not use models when they have adequate empirical data. When they have adequate data, they can simply use them to predict future outcomes. However when empirical data are lacking, that is exactly the situation in which scientists are forced to estimate future risks, on the basis of strongly theoretical and uncertain computer models. Hence, by definition, scientists and mathematicians have limited grounds for claiming they have accurate risk probabilities, when they really face situations of uncertainty (Shrader-Frechette 1993).

Computer modelers often mischaracterize situations of Bayesian uncertainty and risk in one of two ways, (A) and (B). Both uncertainty-related errors, (A) and (B), tend to occur more often when scientists and engineers are overconfident about their knowledge of risky new technologies. Frequently either (A) they misrepresent cases of Bayesian mathematical-scientific *uncertainty* (defined in terms of purely-subjective probabilities) as cases of *risk* (defined in terms of reliable, often frequency-based, probabilities), or (B) they claim that their computer-modeled estimates of risk are more reliable than they are, sometimes because they fail to do uncertainty analysis. Uncertainty analysis is a statistical assessment of the reliability of scientific or engineering judgments about the values attributable to estimates or computer models, often of risk. Whenever such values are untestable, rely on unknowns, or reflect cumulative effects of data variability, uncertainty analysis can assess both random error and bias (Jordaan 2005; Shrader-Frechette 2007:76–112; 2017).

Uncertainty analysis is especially needed when scientists or engineers estimate long-term, inaccessible, or difficult-to-predict harmful effects, such as 10,000-year effects of climate change—or the timing, route, and volume of pollutants that may escape from a hazardous-waste site. Otherwise, experts' well-documented overconfidence, representativeness, anchoring, and other cognitive biases could compromise sound science and threaten public health (Kahneman et al. 1982).

THE FLAWED MIT REACTOR STUDY

Unfortunately, even well-known scientific and engineering analyses, like the classic MIT study of commercial-nuclear-reactor-accident probabilities, may misrepresent uncertainty. For instance, they may commit (A) when they confuse risk and uncertainty by making subjective assumptions about how to quantify public-health risk. They may commit (B) when they fail to do uncertainty analysis. The MIT engineers committed (A) because they made the subjective assumptions that they could rely on purely theoretical calculations, could ignore available empirical data about accidents, could presuppose that control-rod and other reactor-failure probabilities were completely independent, yet then could estimate that nuclear-core-melt-accident risks were only 1/17,000 per reactor-year – that is, about 1 in 5 for all US reactors during their lifetimes. Unsurprisingly, the American Physical Society and US Nuclear Regulatory Commission said they do “not regard as reliable” the MIT “numerical estimate of the overall risk of reactor accidents.” Because the distinguished MIT researchers

did not do any uncertainty analysis, they also fell into error (B) (Shrader-Frechette 2014; US Nuclear Regulatory Commission 1975, 1979).

However, US, Dutch, and other engineers showed that the MIT study errs in ignoring empirical data, exhibiting overconfidence biases, and overestimating nuclear safety. When the other researchers compared actual, empirical, US reactor-accident frequencies (tracked by the US government's Oak Ridge, Tennessee Laboratories), with the MIT predictions for the same 7 events, they showed the actual occurrence rates for all 7 accident types were outside MIT's 90-percent-confidence bands. That is, the MIT authors said these repeated accidents had only a 10 percent probability. Simply checking available empirical data and doing uncertainty analyses could have helped MIT avoid this misrepresentation of uncertainty and underestimate of nuclear-reactor threats to health and safety (e.g., Cooke 1982; Shrader-Frechette 1991, 2007; US Nuclear Regulatory Commission 1975).

BIASED US GOVERNMENT STUDIES OF YUCCA MOUNTAIN WASTE REPOSITORY RISKS

Similar misrepresentations occurred when US *Department of Energy* (DOE) engineers assessed the million-year safety of the proposed Yucca Mountain, Nevada, nuclear-waste repository (TRW 2000). After DOE contractors failed to do uncertainty analysis, then made optimistic predictions about repository safety, scientists from the International Atomic Energy Agency used DOE's own data to do uncertainty analysis. The results were damning. DOE's overconfident estimates of future low risks – based on their estimated low radiation doses from Yucca Mountain – were uncertain by 9-12 orders of magnitude. Yet if they had erred by only 2 orders of magnitude, catastrophic numbers of deaths could occur (IAEA 2001; Shrader-Frechette 1993, 2007).

Both the MIT and DOE misrepresentations of uncertainty arguably have contributed to false-negative biases, false assertions that nuclear reactors are not as dangerous to public health and safety and they really are. They also have contributed to building more expensive, risky nuclear plants, as well as to environmental injustice in nuclear-plant siting. This environmental injustice occurs because US commercial reactors are disproportionately sited in predominantly poor, southeastern US communities, under the false assumption – based on models that misrepresent uncertainty – that these communities are not put at any extra risk. Similarly, Yucca Mountain was sited near predominantly Native American and Latino communities, also under the false assumption – based on models that misrepresent uncertainty – that local communities would bear no higher risk (Shrader-Frechette 2011).

THE SCIENTIFICALLY ERRONEOUS US GOVERNMENT MODELS FOR WEST VALLEY, NEW YORK

West Valley, New York presents another dramatic example of how flawed computer models can provide flawed scientific and public-health analyses. West Valley has been the only place in the US where the country did reprocessing of spent nuclear fuel and, as a result,

it is one of the most hazardous sites in the entire country. However, since the 1970s, when West Valley stopped nuclear-fuel reprocessing, the New York state government, national and local citizens groups, and the US federal government have been fighting over how to solve the West Valley dilemma: West Valley radioactive and toxic wastes are not safe where they are, even for a short time, because of site erosion and because the place is the most radioactively contaminated in the US. However, site remediation – for which the US DOE and the state of New York are responsible – will be very expensive, so neither side wants to pay for moving the wastes to a safer site. The US DOE solution? Misrepresent risk and uncertainty so as to underestimate site hazards, ignore the huge plume of radioactive waste moving toward Lake Erie and drinking-water supplies, fail to do any adequate uncertainty analyses, then issue a 2010 *environmental impact statement* (EIS) that declares the lethal waste to be safe where it is onsite – even for 10,000 to a million years (Napoleon et al. 2008; Shrader-Frechette 2016; US DOE 2010;).

How did DOE come to the strange conclusion that this US site, with more long-lived radioactive contamination than any in the US, could be left alone, largely “as is,” and cause no health harm? DOE made at least three scientifically questionable moves in its computer models. It (1) confused risk and uncertainty; (2) avoided doing any classic uncertainty analysis to assist in decision making, and it (3) arbitrarily redefined the meaning of “uncertainty analysis” so that it could claim to have done this analysis, allegedly showing that by the time lethal amounts of waste migrated, they would cause only minor harm.

West Valley Background

It is puzzling that US government computer modelers claimed that their models showed West Valley would be harmless for the next 10,000 years. Already in 1983, scientists discovered a West Valley plutonium-239 leak that was already 63 feet offsite. It has been traveling through subsurface fractures and sand and is radioactively contaminating Lake Ontario and Lake Erie (source of drinking water for communities like Buffalo, New York) at levels beyond federal radioactivity limits. Given the plutonium-239 half-life of 24,110 years, this leak will cause contamination and risk for hundreds of thousands of years (Napoleon et al. 2008).

Assessing West Valley radioactive dangers, Cambridge, Massachusetts scientists warned in the first decade of the 21st century that “radionuclide doses calculated for a person drinking [local water near the site]...were substantial and well in excess of the federal and state [safety] standards.... [As a result, this West Valley pollution will cause....] up to 334...people...to die of cancer as a result of their exposure to [radioactively] contaminated water from Lake Erie” (Napoleon et al. 2008). “Adverse health effects as well as unnecessary deaths from cancer [will occur] due solely to radiation exposure coming from the West Valley site” [19]. At least 30 years ago, scientists documented that the West-Valley-contaminated local creeks have contaminated Lake Erie (and its drinking-water supplies) which, in turn, have contaminated both the Niagara River and Lake Ontario (Joshi 1988a, 1988b; Napoleon et al. 2008).

Apart from existing contamination of New York water supplies, the West Valley site has a massive groundwater-contamination plume of strontium-90 that not only violates

government safety regulations but also will expand and cause risks for at least another 300 years because of the long strontium-90 half-life. Besides multiple leaks of long-lived, radioactive, groundwater contaminants, West Valley waste-site soil also is eroding at a rate of 1 foot per year, threatening to unearth the shallow land burial of the improperly dumped West Valley radioactive wastes, (Napoleon et al. 2008: 12, 13, 37, 44-45, 54-64, 107).

Mischaracterizing Risk and Uncertainty in West Valley Computer Models

Instead of admitting the severity of the West Valley site risks, in 2010 the US DOE EIS claimed that minor cleanup, plus leaving most of the lethal waste buried onsite, will be safe for the next tens'-to-hundreds of thousands of years. The US DOE concluded that if it merely leaves much of the long-lived nuclear waste onsite at West Valley, without any government-institutional management such as fences, monitoring, and erosion controls, the maximum annual future dose to any person offsite will be only 0.2 mrem or 0.002 mSv – about 1/2500 of normal background radiation. Even with completely uncontrolled erosion, DOE also says that future yearly maximum offsite radiation dose would be only 4 mrem – less than one percent of normal background radiation (US DOE 2010).

The preceding claims are surprising conclusions for at least two reasons. The first reason is that distinguished economists have shown that the least-expensive, long-term strategy is to move West Valley wastes to a safer, drier location (Napoleon et al. 2008). Why doesn't US DOE accept the cheapest long-term solution? The main reason is that annual West Valley Congressional budget allotments from the US DOE cover only minor cleanup and site maintenance, US DOE has been reducing annual West Valley budgets, and US DOE and the Congress have not given the greater, one-time, West Valley funding needed for full site cleanup – which would dwarf annual available, budgeted site monies (Napoleon et al. 2008: 9, 12, 26, 39, 63, 108, 128-130).

The second reason the DOE West Valley claims are surprising is that there is no scientific way to predict such tiny risks and precise radiation exposures, up to a million years into the future. Besides, if future West Valley risks would really be so low, why does the US government today say that it would not allow siting a nuclear-waste facility at West Valley because of its severe erosion problems? Scientific peer reviewers consider US DOE radiation-risk predictions from the West Valley site, including the maximum dose of 0.2 mrem/year, highly unlikely (Napoleon et al. 2008; NYSERDA 2010). Moreover, the US National Academy of Sciences has pointed out that scientists agree that it is impossible to make precise risk predictions about site historical, hydrological, geological, and meteorological events tens of thousands of years in the future (US National Research Council 1995).

But if so, how does the DOE get its risk predictions? A key way that the US DOE's 2010 EIS claims reliable, 10,000-year "predictions" of low risk is that it ignores massive long-term uncertainty and instead employs a largely subjective, "best estimate" set of mostly deterministic predictions about future site safety. It also uses single values, rather than a range of probable values, for model inputs and parameters. Without any documentation or defense of its "estimates," the US DOE next begs the question when it asserts that these guestimated risk-input values are "conservative." Given such question-begging, subjective, risk-

probability estimates, US DOE ignores massive, long-term uncertainty about the site (NYSERDA 2010; Shrader-Frechette 2016; US DOE 2010).

Regarding parameter uncertainty, for example, although the EIS admits that erosion is the main way that site radionuclides are likely to be transported, it gives neither error estimates nor confidence intervals for the parameter values it uses to predict in erosion risk – the most essential of all predictions for ensuring site safety. Yet, US DOE admits that these parameters have a large potential range. For instance, although the EIS shows no gully erosion in the South Plateau over the next 10,000 years, his conclusion is “wholly inconsistent” with the observed topography and observed, long-term, continuing, severe erosion and stream downcutting at the site. In other words, the US DOE conclusions about 10,000-year, site-erosion risk not only ignore long-term uncertainty and fail to have any mathematical justification, but they also contradict existing, short-term (30 years) frequency data on massive site erosion. These are some of the reasons that the long-term, site-parameter predictions of risk in the EIS are not reliable (Shrader-Frechette 2016; US DOE 2010).

Avoiding Uncertainty Analysis of West Valley Computer Models

Thus, despite the dominance of uncertainty in long-term hydrogeological prediction, and despite DOE’s providing EIS uncertainty analyses only for a handful of the hundreds of relevant West Valley parameters, it concludes that the site will be safe for the long-term future. DOE also does no uncertainty analysis of its model predictions, and it ignores uncertainties that arise from factors such as spatial variability at the site (US DOE 2010).

For instance, the US DOE EIS could have done uncertainty analysis of its model predictions, but it did not. Likewise it could have qualitatively assessed the uncertainties in its main computer model – a landscape-evolution model – by listing all major assumptions, questionable predictions, idealizations, and application problems. Again the EIS did not do even this qualitative analysis. Instead it used a crude landscape-evolution model for long-term site prediction – although scientists agree they are unsuitable for long-term prediction. As in the earlier Yucca Mountain case, this is another example of risk assessors and computer modelers using a fundamentally “explanatory” model of a site as if it were a “predictive” model (Shmueli 2010). Because the EIS admits such explanatory, landscape-evolution site models cannot predict locations of streams, gullies, and landslides; cannot address stream wandering, over time; and cannot predict knickpoint erosion that is causing rapid downcutting erosion of stream channels and increased gullying, it is puzzling that the EIS used such admittedly crude models for its claimed precise, long-term predictions (Shrader-Frechette 2016).

Similarly, the EIS used a crude, one dimensional model of groundwater transport at the site to predict future radiation doses to humans, for 10,000-1,000,000 years (US DOE 2010), although such models cannot be validated or verified (Bredehoeft 2005; Bredehoeft and Konikow 1992), and although a three-dimensional model likely would have been more reliable than the US DOE one-dimensional model. Yet, never did the EIS present a compelling argument for why it chose to use simplified one-dimensional flow-and-transport models for the purposes of calculating something as important as long-term radiation dose. Never did the West Valley EIS defend its generating nearly worthless computer-model

predictions whose reliability has never been assessed. In fact, even the EIS short-term computer models of the site are nearly worthless, because none of them is able even to correctly predict current-time gully erosion. Yet gully erosion is the principal surface threat to the radioactive wastes. Never did the EIS do model verification or validation by comparing model output with actual field data available for the short term. For all these reasons, the US DOE decision to avoid uncertainty analysis is highly questionable (Shrader-Frechette 2016).

Relying on Non-Standard Accounts of Classic Scientific Terms and Methods

The US DOE 2010 West Valley EIS also erred in failing to employ the standard scientific meaning of terms such as “uncertainty analysis” when it used them. In other words, rather than admit all these sources of West Valley EIS uncertainty, and rather than do an uncertainty analysis, the DOE West Valley EIS simply redefines various scientific terms in ways that cover up the flaws in the document and the failure of the authors to do standard uncertainty analysis. For instance, while its use of the term “best estimate” suggests a reasoned, empirical assessment, the EIS and computer model use the term in a way that is contrary to standard scientific use. Scientists usually employ the term to mean the average or mean of a distribution or some other optimum, such as a median. However, the DOE EIS uses “best estimate” to mean merely some estimate, subjectively considered by the authors (without any justification provided) to be conservative (US DOE 2010). Yet nowhere does the EIS explain or argue why its’ supposed analyses are conservative. Indeed, given all the gratuitous guestimates and undocumented claims, it is impossible to check the alleged conservatism of the EIS scenarios (Shrader-Frechette 2016).

One alleged conservative best estimate of US DOE, for instance, is that “the probable maximum flood floodplain is very similar to the 100-year floodplain” (US DOE 2010). Yet by definition, the maximum flood over 50,000 years has more extreme, therefore more dangerous, values than over 1/500 of that time span, namely 100 years. Likewise, the EIS says it provides a conservative estimate of West Valley radiation in drinking water because its “drinking-water dose analysis conservatively assumes no radionuclide removal in the water treatment system” (US DOE 2010). Yet such an assumption is not conservative, but typical. US water-treatment facilities typically do nothing except add chlorine to the water to kill bacteria. They are not equipped to remove radionuclides or any other contaminants. Hence to assume no such removal is not conservative but typical (Shrader-Frechette 2016).

Similarly the EIS says it presents a conservative “best estimate” for West Valley radiological accidents because it presents the estimated worker “accidents and fatalities that could occur from actions planned for each of the proposed alternatives. These estimates were projected using data from DOE’s historical database for worker injuries and fatalities at its facilities” (US DOE 2010). Yet employer databases typically underestimate health problems and accidents, both because they include no long-term follow-up of workers and because workers are reluctant to admit either their radiation accidents or excessive dose levels, because they fear losing their jobs. Given the EIS misnomer of “best estimates,” the pro-nuclear scientific peer reviewers of the EIS warned: “it appears to us that a more apt description” of many of these alleged EIS “best estimate” cases would be “nominal and non-conservative” (Bredehoeft et al. 2006).

Likewise the West Valley EIS repeatedly claims to have presented an uncertainty analysis of its conclusions. Yet according to standard scientific usage, an uncertainty analysis assesses the degree to which any particular conclusions and input parameters are reliable. The West Valley EIS, however, does not employ the term “uncertainty analysis” in this way.

Instead, as the pro-nuclear scientific peer reviewers point out, the West Valley EIS uses this term to mean simply presenting several different deterministic cases – in fact, only two of them. The reviewers warn that although the EIS “considers presenting three sets of cases to constitute an analysis of uncertainty,” it “cannot substitute for a comprehensive uncertainty analysis” (Bredehoeft et al. 2006; see Shrader-Frechette 2016). Because nothing in the EIS justifies choosing these two sets of deterministic, non-probabilistic assumptions rather than others, because there is no probabilistic analysis that could provide the basis for quantifying uncertainty, the EIS provides little basis for confidence in the quality of its conclusions, little basis for precisely or reliably understanding the contributors to uncertainty (Shrader-Frechette 2016).

QUESTIONABLE TREATMENT OF UNCERTAINTY IN COMPUTER MODELS AND HOW TO AVOID IT

Perhaps the most scientifically and ethically worrisome thing about the West Valley modelers’ treatment of risk and uncertainty is that essentially the same US government agencies, responsible for US public health and safety from ionizing radiation, have been making the same fundamental mathematical and scientific modeling mistakes for nearly half a century—at least since the 1975 flawed studies already mentioned. The longevity of such errors suggests it is especially important to develop ways to avoid such flawed scientific modeling, especially modeling that underestimates serious public-health threats.

Epidemiologist David Michaels, former President Obama’s assistant secretary of labor, seems to agree. He claims the US health-regulatory system is broken. As a result, he says flawed science and engineering dominate it. He shows how unscrupulous product-defense, contract-research, and private consultants, along with US regulatory agencies like DOE – that are dominated by the entities that they regulate – misuse analytic techniques, ignore dangerous uncertainty at places like Yucca Mountain, “manufacture” uncertainty about obvious and certain product/pollutant harm, control the scientific literature, and thus derail needed protections and regulations (Michaels 2008).

Whether or not Michaels is correct –and many US scientists say that he is, e.g., (Cranor 2011; McGarity and Wagner 2008; Shrader-Frechette 2014), there are ways to make computer modeling of health and safety threats better. Especially any time science is used in ways that affect human welfare or regulations, there should be clear standards for valid science, risk assessment, and computer models. Yet, for more than half a century, there have been clear legal and ethical requirements for research affecting human subjects, but there no comparable legal, scientific, and methodological requirements for research – like computer models used in human-health risk assessment – that affect human welfare (e.g., EPA 2006: 6160).

In failing to articulate scientific standards for welfare-affecting or regulatory research, federal agencies like US EPA, US DOE, and US NRC err. The whole point of science is that

its principles are universal, not just case-specific. As any good scientist knows, two key factors that undercut scientific validity are using low-power or small-sample studies and short-term studies – both of which make studies likely to falsely conclude that there are no (or limited) negative health effects from some exposure (Shrader-Frechette 2016).

Indeed, a primary failing of studies like US DOE 2010 West Valley risk assessments and computer models are that they both frequently ignore short-term frequency and empirical data showing that their risk-assessment models likely are wrong, and they never admit the impossibility of long-term prediction in the absence of long-term data. Thus, one obvious scientific-default rule might be: “Accept no low-power, short-term, or million-year studies claiming minor harmful impacts, unless these claims are clearly scientifically substantiated and approved by independent peer reviewers and the predominance of all available frequency data” see (Moyer and Finney 2005: 307). Versions of this rule are enshrined in virtually all statistics, public-health, and epidemiology textbooks, yet regulators do not require it, and studies like those from US DOE violate it (Shrader-Frechette 2016).

Such scientific rules are particularly needed for two main reasons (Shrader-Frechette 2016). One reason is that both the US National Academies of Sciences, the US EPA (external) Science Advisory Board, and other scientists have urged government to adopt specific scientific norms for all research used for regulatory purposes – and to provide a mechanism to ensure compliance with these norms. However, such norms arguably are needed for any research related to regulatory protection of humans from any dangerous pollutants – including nuclear waste (EPA Science Advisory Board 2000; National Research Council 2004; Oleskey et al. 2004).

Another reason that scientific and computer-modeling rules are needed is that both Congressional and government studies reveal that regulated entities routinely submit scientific studies – for use in setting regulations – -that are severely scientifically flawed (Shrader-Frechette 2016). They typically are short term, or low power studies, or have other obvious false-negative biases against finding any harm from their own industrial products or pollutants (EPA Science Advisory Board 2000; US House of Representatives 2005). However, instead of addressing these well documented biases, EPA and other government agencies ignore these scientific flaws that lead to ethical bias (EPA 2006). Yet as the National Academy warns, “a study cannot be ethically acceptable if it is scientifically invalid” (National Research Council 2004).

CONCLUSION

As these MIT, Yucca Mountain, and West Valley computer models reveal, flawed methods may be used not only by corporations, seeking to protect profits, but also by allegedly democratic governments that appear unwilling to spend the necessary monies to actually protect citizens from technological risks. Such government misuse of science and computer modeling may be even more deadly than corporate misuse of modeling because typically citizens cannot sue government, the way they can sue corporations or citizens who harm them. Implementing norms for regulation-related and welfare-related risk assessment and computer modeling is thus essential.

ABSTRACT

The ingestion of raw or undercooked pork poses a public health risk, since pork is the main transmitter of parasites, which include the protozoa *Toxoplasma gondii* (*T. gondii*) and the helminths *Trichinella spiralis* (*T. spiralis*) and *Taenia solium* (*T. solium*). These three ‘T’ porkborne parasites have been responsible for most of the porkborne illnesses throughout history; they are still endemic, and therefore are important public-health concerns, in developing countries. In Mexico, these three ‘T’ porkborne parasites are considered re-emerging parasites, and they represents a risk for the population that consumes large quantities of pork. Currently, inspection procedures are effective in eliminating the majority of the risks from *T. spiralis* and *T. solium* in certified slaughterhouses, due to the training of inspectors in the detection of tissue cysts. However, there are still clandestine slaughterhouses that do not have adequate surveillance methods to identify these parasites. Furthermore, for *T. gondii* no suitable methods for post-slaughter detection are available, where intervention measures at the animal level may be key to successful prevention. Early detection of the parasite is not easy, and the implementation of molecular techniques must be improved and made available mainly in endemic areas, in order to establish an accurate diagnosis, because isolation procedures are long, more expensive and often not sufficiently sensitive. The objectives of this chapter are to describe the epidemiological situation of these three

parasites transmitted by pork in Mexico, outline the main lines of prevention, and describe the molecular methods that can be used for the early and accurate detection.

Keywords: pig-meat, zoonosis, parasites, Mexico, molecular detection, prevention

INTRODUCTION

Foodborne zoonoses have been estimated to annually affect 10% of the global population, among which zoonotic parasites constitute an important class of aetiological agents [1]. Foodborne parasites are expected to have a strong impact on public health in the future, particularly with the increase in meat consumption that is taking place in the world and the recognition that billions of people lack basic water services [2]. Pork is one of the main transmitters of parasites that include the protozoa *Toxoplasma gondii* (*T. gondii*) and the helminths *Trichinella spiralis* (*T. spiralis*) and *Taenia solium* (*T. solium*). These three ‘T’ parasites have been responsible for most porkborne illnesses throughout history; they are still endemic, and therefore are important public health concerns, in developing countries [1]. They are important because pork has long been the most consumed meat globally, and the projections of the future global pork demand remain robust [3]. The disability adjusted life-years (DALYs) have been estimated for human cysticercosis, toxoplasmosis and trichinellosis, with 2.78 million DALYs (95% UI 2.14–3.61 million), 825,000 DALYs (95% UI 561,000–1.26 million) and 550 (95% UI 285–934), respectively [4]. The United States has improved demonstrably over recent decades in pork safety due to the changes in swine production methods. The implementation of intensive confinement production systems has eliminated the risk of foodborne parasites [5]. The environment in which animals are kept determines the course and severity of disease expression; a highly contaminated environment for animals with a weakened immune system often tips the balance and makes a disease clinical [6]. The potential sources of infection at the farm level for these three parasites include water, feed, soil/organic material contaminated with oocysts or eggs, feed contaminated with infected animal tissue, and exposure to and ingestion of tissue from rodents, pigs, or wildlife carcasses [7]. The culinary preferences for fresh, slightly cooked, and ready-to-eat food and the increasing demands for meat in developing countries are increasing the risks posed by foodborne parasites [8]. In addition, pigs raised in outdoor systems inherently confront higher risks of exposure to foodborne parasites, particularly *T. gondii* [5].

Several endemic countries (such as some countries in Asia, Eastern Europe, and South America) cannot avoid human infection due to inadequate quality control in meat production [2]. In México, reporting the occurrence of these three parasites is considered mandatory by monthly notification to the official dependencies of animal health of the country [9]. According to the Mexican regulation (NOM-SSA1-2004), pork must be free of *Trichinella spiralis*, *Taenia solium* and other parasites; however, trichinoscopy is not mandatory [10]. Regarding, *T. gondii*, there are no official regulations that required the identification of tissue cysts in the carcasses. In the country, the Federal Inspection Type Certification, (abbreviated TIF), is an acknowledgment granted by SAGARPA (Secretary of Agriculture, Livestock, Rural Development, Fisheries and Food), that performs a thorough inspection procedure and supervises and traces industrial establishments that are dedicated to produce, store, sacrifice,

process and distribute all kinds of meats and their derivatives. The TIF recognition opens the possibility of international trade, since these establishments are the only ones eligible to export. Currently, in Mexico there are 457 TIF slaughterhouses where the surveillance of the meat is guaranteed [11]. However, in local markets in the central region of Mexico, it has been reported that 11.3% of the meat sold comes from pigs raised at home, which are illegally slaughtered [12]. In rural regions of Mexico, it is common to raise backyard pigs without adequate sanitary conditions, and these animals are slaughtered in unhealthy facilities that are not inspected for pathogens that may be encysted in the animal tissues. Unfortunately, there is no record of the illegal slaughterhouses established in Mexico, where proper inspection of the pig carcasses is not carried out, representing a risk for consumers. In addition, it has been shown that methods of direct observation of meat have low sensitivity, so the frequency of these porkborne parasites in Mexico may be underestimated [13]. Efforts to maintain innocuous pork meat ensure that the population is free to acquire these parasitic infections. The implementation of efficient, accessible, and controllable inspection policies for livestock, slaughterhouses, and meat processing and packaging companies is highly recommended [14].

In this chapter, we present epidemiological data reported for these three “T” pork parasites of public health interest in Mexico. Additionally, we described the main molecular methods used for the detection of these parasites in pork meat, as well as the prevention measures.

METHODS

Epidemiology of *Taenia solium*

Taenia solium is a hermaphrodite cestode parasite that infects humans and pigs. Worldwide, it is estimated that approximately 2 to 3 million people are infected with *T. solium*, and it is thought that some 50,000 people die annually from this parasitosis due to complications in the nervous system or heart failure [15]. *T. solium* is endemic in tropical regions of the world (Latin America, Southeast Asia and Africa). Normally, the cycle life of *T. solium* involves two hosts (human and pig) in which this parasite completes its life cycle. The disease is known as taeniasis and is more common in rural communities where domestic pigs are raised under free conditions, allowed to roam in the backyards and feed on fecal matter deposited by people in backyards because of a lack of sanitary infrastructure [15, 16]. Humans become infected by *T. solium* when eating inadequately cooked pork that contains the larvae. Once consumed, the larvae restart their development to the adult forms in the small intestine of humans, specifically the duodenum (5 to 12 weeks of patency). *T. solium* attach to the wall of the small intestine using the scolex armed with 4 suckers and 2 rows of large and small hooks [15, 16, 17]. Each segment or proglottids of *T. solium* have different degrees of development (immature, mature and gravid). The last segments are called gravid proglottids that contain infective eggs; these segments detach from the strobila (the main body of the parasite) and are shed in the environment through the feces. Adult *T. solium* can eliminate up to 300,000 eggs per day. These segments remain active and show movements. *T. solium* could reach 2 to 7 meters in length and live less than 5 years but occasionally could persist nearly 25 years. The infection of adults with *T. solium* is often asymptomatic, but the

presence in many adults can cause mucosal irritation, abdominal pain, diarrhea, constipation, weight loss and obstruction of the intestinal lumen [15, 16, 17].

The natural intermediate host for *T. solium* is the pig; however, the parasite can occasionally be found in dogs, cats, sheep, camels, monkeys and humans (Figure 1, *Life cycle image courtesy of DPDx*) [18]. Pigs are infected through the consumption of the eggs of *T. solium* scattered by wind or rain that contaminate the water or their food. In the interior of the host, the embryo is activated and leaves the egg, penetrates the intestinal mucosa, enters blood circulation and disperses to other tissues between 24 and 72 hours after ingestion [15, 18]. Once in the tissue, the embryo is transformed into cysticerci with the shape of an ovoid vesicle [18]. In the pig, the cysticercus is located in the striated or cardiac muscle. In humans, cysticerci can invade different types of muscle (striated and cardiac), the central nervous system (brain), the subcutaneous tissue and other tissues of the host, such as the liver, lungs, abdominal cavity and eye orbit [15, 18]. The most common cases of cysticercosis in humans are detected in the central nervous system. The presence of cysticerci in the tissue unchains many mechanisms in the human body such as inflammation, fibrosis and some calcification. In the brain, this immunological reaction produces neurological signs such as epilepsy, seizures, headaches, nausea, visual disturbance, focal weakness, and paresthesias. The neurological form of the disease is called neurocysticercosis and is the most serious form of the disease [18, 19]. Regardless of the source of the infection, the lack of hygienic habits, such as washing hands after going to the bathroom and before consuming meals, are the main reasons for the presentation of cysticercosis in humans (*Taenia* and *Cysti*). Other factors, such as the use of wastewater for irrigation or the consumption of contaminated water from rivers, could contribute to the spread of the eggs [18].

Taenia solium in Pigs in Mexico

In Mexico, the epidemiological studies that have focused on binomial taeniasis/cysticercosis in humans. However, most of studies were conducted prior to the year 2000. At the national level, the actual prevalence of this parasitosis associated with poverty conditions is still unknown. Many of the existing studies carried out in Mexico have been isolated, focusing on some states, and few have jointly evaluated the positivity of people and pigs. Table 1 shows the results of different studies in which infection by *T. solium* cysticerci was diagnosed in pigs reared in rural communities in Mexico. The highest prevalence of pigs infected by cysticerci was found in pigs from Yucatán State (southeast region), with a prevalence of 23 to 35% [20, 21, 22]. In central Mexico, a prevalence of 25% was reported from Hidalgo State [23] and 2.6% to 13.3% was reported for the state of Morelos [24, 25, 26, 27]. For the Pacific coast, prevalence rates of 6.5% and 17.7% were reported for Michoacan and Guerrero State, respectively [28, 29]. In Mexico it is estimated that 2.1 million pigs live in rural areas, inside backyard systems [30]. Considering the percentage of infected pigs in some studies conducted in the country, the risk of acquiring taeniasis and cysticercosis is high.

Approximately, 4,328 cases of human cysticercosis have been reported between 2000 and 2010 [31]. Recently, in 2017, 227 and 179 cases of Taeniasis and Cysticercosis have been reported, respectively. In the January-October period of 2018, 139 cases of Taeniasis and 187 cases of Cysticercosis have been reported [32]. The persistence of cases diagnosed in humans in different states of the country suggests that the prevalence of this disease in pigs reared in backyards could be underestimated. In Mexico, the lack of sanitary infrastructure, the availability of decent housing with latrines, the low economic income of families in rural communities, the backyard rising of animals for self-consumption and the saturation of health centers contribute to the persistence of this parasitosis.

Epidemiology of *Toxoplasma gondii*

Toxoplasma gondii is an apicomplexan protozoan intracellular parasite with a widespread distribution in both developed and developing countries [33]. *T. gondii* has veterinary and medical importance, because it may cause abortion or congenital disease in its intermediate hosts [34]. Additionally, *T. gondii* can cause severe illness in immunocompromised individuals [35], and ocular toxoplasmosis is frequently observed in immunocompetent patients [36]. Felids are the only definitive hosts in which the parasite can complete its sexual cycle and spread millions of oocysts into the environment. Although the number of oocysts produced is a key element in environmental contamination and consequently in parasite transmission, *T. gondii* is also able to rely on its asexual cycle in all warm-blooded animals (mammals and birds) and humans [35]. Initial infection of a host is usually accomplished by the rapidly replicating form of the organism called tachyzoites. However, in an immune competent host following the activation of the immune system, the tachyzoites undergo a conversion to the slowly replicating form of the organism called bradyzoites, which cluster to form tissue cysts. These tissue cysts can persist in the brain and other organs for extended periods of time without the generation of an apparent immune response. At various times, a portion of these tissue cysts can reactivate into tachyzoites and, if the immune response is adequate, subsequently reconvert into bradyzoites containing tissue cysts. Through these interconversions, *T. gondii* can establish life-long persistence in immune competent hosts [33].

There are two major modes of transmission of *T. gondii*: infection may occur by the ingestion of food or water contaminated with oocysts excreted by infected cats or by ingesting uncooked or undercooked meat containing tissue cysts (Figure 2, *Life cycle image courtesy of DPDx*). The proportion of the human population that acquires an infection by the ingestion of oocysts in the environment or by eating contaminated meat is not known, and there are no tests available that can determine the infection source. However, sero-epidemiologic data suggest that ingesting improperly cooked meat containing *T. gondii* is a major source of infection for humans in the United States [37, 38]. In addition, pregnant women in Europe identified meat ingestion as the major source of *T. gondii* infection (30–63% of cases) [39].

It has been reported that in meat-producing animals, tissue cysts of *T. gondii* are most frequently observed in these tissues of infected pigs, sheep, and goats, and are less frequently in infected poultry, rabbits, dogs, and horses, with pork being the major source of *T. gondii* infection [34]. These animals harbor tissue cysts, and human consumers can be infected by ingestion of these cysts in raw or undercooked meat [40]. Virtually all edible portions of an animal can harbor viable *T. gondii* tissue cysts [41], and tissue cysts can survive in food animals for years [40]. It has been shown that a single *T. gondii* oocyst is capable of producing an infection in pigs, and among the most parasitized organs with tissue cysts are the tongue, brain and heart [42].

The reduction of the risk of *T. gondii* infections in pigs is possible, using intensive farm management with adequate measures of hygiene, confinement, and prevention [34]. In contrast, pigs reared on organic farms have shown to have a higher *T. gondii* prevalence than pigs from conventional farms [35].

The first report of *T. gondii* in pigs in Mexico was in the central region, where they analyzed 6 to 10-month-old pigs weighing 90-100 kg from an abattoir of Morelos State, and they found a prevalence of 8.9% using ELISA [45]. Another study conducted in Jalisco State (west region that borders the Pacific Ocean), they analyzed 48 pork samples from butcher shops and found that all the samples were negative by histology and by PCR; however, a positivity of antibodies against *T. gondii* of 2.1% in pork meat was detected through bioassay [46]. In Veracruz State (eastern region and the coastline on the Gulf of Mexico) a seroprevalence of 45.3% was reported in domestic pigs raised in backyards using the Microscopic Agglutination Test (MAT), showing that a tropical-humid climate, feeding with leftovers, storing pig food in the owner's home, and free ranging was associated with *T. gondii* seropositivity in pigs [47].

Table 2. Studies of *Toxoplasma gondii* in pigs from Mexico

Toxoplasma gondii					
Sample	Origin	Assay	Positivity	State	Reference

ND: Not data.

In the southern region, the Yucatan State (northern part of the Yucatan peninsula) has carried out the largest number of studies of *T. gondii* in these animals, finding high seroprevalences in pigs reared on farms as well as pigs reared in backyards. A study in this region analyzed the infection dynamics of *T. gondii* in two fattening pig farms exposed to high and low cat densities and found that 100% of finished pigs had contact with the *T. gondii* regardless of the relative density of the cats [48]. Another study in Yucatan, reported a positivity of *T. gondii* DNA in 50.8% of the blood samples and a seroprevalence of 96% in pigs reared on farms, indicating a high circulation of the parasite [49]. In addition, backyard pigs have reported seroprevalences of 75% from the same region [50]. The high circulation of *T. gondii* in pigs intended for human consumption in Yucatan has led to investigations of the presence of DNA in pork using PCR. Regarding the presence of the parasite in pork, the first report in the southeast of Mexico found a positivity through an nPCR of 23.2% and 7% for samples of tongue and loin tissue, respectively [51]. Subsequently, the parasitic burden of *T. gondii* in Mexican hairless pig (*Sus scrofa*) tissues using quantitative real-time PCR (qPCR) was determined, finding a positivity of 5.3% of the tissue samples with an average of 2.5 ± 2.71 , 0.26 ± 0.39 and 0.31 ± 0.37 parasites per gram for the leg muscle, heart and tongue tissue, respectively [52]. In Oaxaca State, a seroprevalence in pigs raised in backyards of 17.2% and in pigs raised on farms of 0.5% was reported, confirming that the management system (outdoor vs. indoor with biosecurity) is a key factor in the epidemiology of swine toxoplasmosis [53]. The relevance between these studies is that the southern region is endemic to toxoplasmosis, with a high prevalence in the human population and in different animal species [54].

Epidemiology of *Trichinella spiralis*

Trichinella is one of the most widespread parasites infecting people and other mammals all over the world in most climates, except for deserts [55]. Trichinellosis infection follows the ingestion of raw or undercooked meat containing *Trichinella* larvae [56], mainly from pigs, wild boar or horses [57, 58]. *Trichinella spiralis* (*T. spiralis*) has a cosmopolitan distribution, and it affects domestic and wild mammals [59]. In Central and South America, the etiological agent of human trichinellosis has been reported to be *T. spiralis*; however, only in a few cases has the parasite species been properly identified [60]. Its clinical manifestations are not specific; thus, the diagnosis of trichinellosis is not easy to make [61]. The life cycle begins when the larvae are released after gastric digestion and mature into adult worms that penetrate the mucosa of the intestine. After fertilization, the female sheds new larvae that disseminate throughout the host to find their definitive location, the striated muscle, where they encyst. This larval migration may result in severe lesions, particularly when larvae migrate to the heart or the brain [55]. Encystment is completed in 4 to 5 weeks, and the encysted larvae may remain viable for several years. Ingestion of the encysted larvae perpetuates the cycle. Rats and rodents are primarily responsible for maintaining the endemicity of this infection. Carnivorous/omnivorous animals, such as pigs or bears, feed on infected rodents or meat from other animals (Image 3, *Life cycle image courtesy of DPDx*).

Worldwide, data from 1986 to 2009 implicated domestic pigs as the major source of infection (53%) in outbreaks [62], most of them in Eastern Europe and Argentina, where the traditional small, “backyard” rearing of pigs for household and local use often involve high risk rearing practices, especially the feeding of food waste. Although commercially produced pork under controlled management now accounts for approximately half of the world’s pork production, the demand by consumers, especially in Europe and North America, for free-range pork is increasing [63]. In addition, Trichinellosis is common in some rural areas of South America and Asia but is quite infrequent in urban regions [55]. In Mexico, 453 human cases of trichinosis have been reported from 1893 to 1995, which were confirmed by the finding of larval *T. spiralis* in diaphragm tissue. Chihuahua State, have been reported the largest outbreak in humans, which was associated with the consumption of pork sausage, even though the anatomical parts of the infected animals presented health check seals [64].

In pigs, very few studies have found pigs infected with *T. spiralis*; however, these data are not reliable since they have not been investigated in other states of the country, especially in production systems with unsanitary conditions [65]. Despite the scarcity of studies on *T. spiralis*, so far in 2018, there have been 9 cases of trichinosis in the human population in Mexico [32]. In rural areas of Mexico, it is common to have pigs as part of the family economy. Unfortunately, pigs are left to breed freely, and they go where they can find food, which is in spaces where there is garbage and the presence of the domestic rat, which is part of the transmission cycle of this parasite (rat-pig-human) [66]. In addition, the clandestine slaughter of backyard animals is frequent [67].

Trichinella spiralis in Pigs in Mexico

Most of the studies on pigs are very old. In a review, from 1909 to 1999 there was a positivity of 0-6% of *T. spiralis* in pig carcasses, mainly from trichinoscopy and artificial digestion techniques. In 1989, samples from backyard pigs were analyzed by ELISA, and

seroprevalences of <1%, 14% and 24% were found for the state of Michoacan, Veracruz and the State of Mexico, respectively [68]. However, there have been few states where these investigations have been made, mainly in Mexico City, the State of Mexico, Tamaulipas, Jalisco, Sonora, Michoacan, Veracruz and Zacatecas [60]. Recent epidemiological studies of *T. spiralis* in pigs are scarce, which could contribute to an underestimation of the occurrence of this parasite in pigs destined for consumption, especially those that are reared in backyards and do not have adequate sanitary conditions, representing a risk for consumers. The few studies that have been conducted on *T. spiralis* in pigs are located in the center of the country (Table 3). One of the studies that analyzed pork samples from butchers and local markets, found all the negative samples through trichinostomy [69]. Another study, used serological tests (ELISA and Western blot) and found a seroprevalence of 12.4% in farm and backyard pigs [70]. The last report we have analyzed samples of pork sausage, finding a positivity of 3.4 and 4% by artificial digestion and by trichinostomy, respectively [65].

Table 3. Studies of *Trichinella spiralis* in pigs from Mexico from the year 2000 to date

Trichinella spiralis

Diagnostic Methods for the Detection of Pork Parasites

Diagnostic Methods of Taenia solium in Pork

At the field level, several detection methods of *T. solium* in pigs are used, including the following: 1) Palpation. Tactile inspection is made in search of cysticerci in the body of the pigs and can be performed before the animals are slaughtered. This method consists of palpating the surface of the tongue to determine the presence of nodules of *T. solium* cysticerci. It has been reported that this method has a sensitivity of 70% and a specificity of 100% [71]. 2) Direct observation. Direct inspection of organs and pig carcasses in search of cysticerci and is carried out during the slaughter stage of animals at certified slaughterhouses. This inspection is carried out by trained veterinary personnel for this purpose [29]. 3) ELISA and Western blot. These techniques allow the detection of antibodies against *T. solium* in samples of serum from pigs. The Western blot technique is commonly used as a confirmatory test due to its high sensitivity (97%) and specificity (100%) [72]. The ELISA demonstrated a sensitivity of 83.7 to 86% and a specificity of 95.7 to 95.9% [73]. 4) Ultrasound. This method consists of observing the presence of cysticerci through portable ultrasound equipment by examining the anatomical regions where cysticerci is located, offering greater sensitivity than

visual inspection and palpation. This technique can be applied in both live animals and animal carcasses [74].

Diagnostic Methods of *Toxoplasma gondii* in Pork

In Mexico, *T. gondii* is not among the mandatory inspection diseases in slaughterhouses. However, the main diagnostic tests for this agent are the following: 1) Serology. This method allows for the detection of antibodies in animals. Among the serological tests used for the rapid diagnosis of toxoplasmosis there is an ELISA and MAT. In addition, Western blot (sensitivity of 84.7% and a specificity of 96.7%) [75] and the Indirect immunofluorescent antibody test (IFAT) could be employed to diagnose of this disease [76]. The latter has been used with a cut-off point of 1:64 and in the 80% of the positive cases, and it has been possible to isolate *T. gondii* by inoculation in mice [77]. Currently, there are commercial ELISA kits for the detection of antibodies against *T. gondii* in porcine serum samples [78]. With respect to the detection of *T. gondii* in pork samples, the MAT has been proposed for examining tissue fluid and has had good results for detection [79]. 2) Molecular biology. With respect to molecular diagnosis, PCR variants have been developed as a real-time PCR, PCR point for the detection of *T. gondii* in blood and tissue samples [80] and nested PCR [81]. In addition, a protocol that includes the magnetic capture of *T. gondii* DNA and a real-time PCR have been developed, which examine large samples of pork (100g) with a limit of detection of 230 tachyzoites, and this method has been validated by ISO 17025 certification [82, 83].

Figure 3. Life cycle of *Trichinella spiralis* (image courtesy of DPDx) www.cdc.gov/parasites/(<https://www.cdc.gov/parasites/>).

Diagnostic Methods of Trichinella spiralis in Pork

The main techniques used for the detection of *T. spiralis* in pork are the following: 1) Trichinoscopy. This involves examining a sample of tissue in which the cystic form of the parasite is observed placed between two sheets of glass under a microscope. This method is applied in the slaughterhouses but show low sensitivity when parasitic loads are less than 2 larvae per gram of meat [84]. 2) Artificial Digestion. This technique consists of dissolving the muscle tissue using pepsin, protease and hydrochloric acid to detect the encysted larvae of *T. spiralis*. Currently, there is a commercial kit for this purpose (PrioCHECK™ Trichinella AAD Kit) that complies with international standards and produces a faster and less risky digestion for operators compared to the conventional method [85]. 3) Serological tests. ELISA assays and immunochromatography have been developed and applied in research but not for field-level diagnosis. However, these tests have been effective for the detection of *T. spiralis* in natural and artificially infected pigs [86, 87]. 4) Molecular biology. As in other infectious agents, there are protocols to perform conventional PCR, real-time PCR and loop mediation isothermal amplification to detect *T. spiralis* in naturally infected wild and domestic pigs [88, 89].

Prevention

Prevention implies taking measures at different levels, both in breeding and surveillance systems, as well as in the personal hygiene habits of people who consume pork. Some measures can be used to reduce the risk of infection for the consumption of infected meat in rural communities where pigs are maintained in backyard systems [18, 90, 91]:

- *In the backyard system.* Keep pigs raised in barnyards made with local materials and that prevent the access of pigs to areas that could be contaminated with pathogens such as *Toxoplasma gondii*, *Taenia solium* and *Trichinella spiralis*. Avoid areas where pigs could be in contact with cats and mice. Do not implement the outdoor bathroom.
- *Personal habits.* Implement personal hygiene habits, such as washing hands with soap and water before eating, after going to the bathroom and after handling raw, meat as well as washing hands after handling pets, such as like cats.
- *Food preparation.* Cook pork meat at a temperature of 71°C before consumption and avoid ingesting half-cooked meat; wash and disinfect raw fruits and vegetables and consume UV-treated water or boil and wash all kitchen utensils that have had contact with raw meat. Keep food out of reach of cats, and avoid the consumption of meat and organs such as the tongue and viscera that have visible nodules.
- *Personal health.* Deworm twice a year. All members of the family must be dewormed.

With simple actions implemented in communities with backyard systems, the risk of infection can be greatly reduced, and this ensures that backyard systems are a safe source of protein for people.

ABOUT OUR RESEARCH

In our experience, we carried out studies of *T. gondii* in samples of serum and tissue from pigs in southeastern Mexico. We will describe the methodologies of *T. gondii* detection that we carried out in our laboratory.

Determination of Anti-Igg Antibodies against *T. Gondii* through an Enzyme-Linked Immunosorbent Assay (ELISA)

Blood samples from the cava vein (Vacutainer tubes without anticoagulant) of pigs were collected at slaughter, and the samples were kept in refrigerated until they reached the laboratory. To obtain the serum, the samples were centrifuged for 10 min at 448 g. The serum samples were individually labeled and stored at -20°C until they were processed. The presence of IgG specific antibodies against *T. gondii* was determined using an indirect ELISA test (Human-GmbH, Wiesbaden, GER). The technique has been adapted according to Figueroa-Castillo [92] using a secondary antibody, anti-swine IgG-HRP (Catalog no. J3007, Santa Cruz, Inc., CA). The serum samples were evaluated at a concentration of 1:100, and IgG secondary antibodies were used at a dilution of 1:5000 [48]. A commercial normal swine serum (Catalog no. B2613; Santa Cruz, Inc., CA) was used as a negative control, and a serum from pigs previously tested by nested PCR (nPCR) as positive (in tissue sample), and an ELISA seropositive was used as the positive control. The optical density was measured at 450 nm using a spectrophotometer (xMark, Bio-Rad). The cutoff point was the average of the negative control plus three standard deviations.

Molecular Test

DNA Extraction from Pork Samples

DNA from tissue samples was predigested in pepsin solution, which was previously described (Table 4) [93]. Then, the protocol of the commercial kit, DNeasy Blood and Tissue (QIAGEN GmbH, Hilden, Germany), was followed. To assess the absence of endogenous inhibitors for PCR amplification, a housekeeping gene, glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was analyzed in each DNA sample with real-time PCR [94].

*Protocol for the Detection of *T. gondii* DNA in Pork Samples through a Nested Polymerase Chain Reaction (nPCR)*

After the DNA extraction step, nPCR was performed to amplify a fragment of 390 bp of the SAG1 gene (encoding the main surface protein of *T. gondii*) [81], using a 96-well Veriti thermocycler (Applied Biosystems). The primers used were external forward 5'-GTTCTAACCACGCACCCTGAG-3' and external reverse 5'-AAGAGTGGGAGGCTCTGTGA-3'. In the second amplification, the internal primers used were inner forward 5'-CAATGTGCACCTGTAGGAAGC-3' and inner reverse 5'-GTGGT TCTCCGTCGGTGTGAG-3'. The first amplification conditions were as follows: 1X Colorless GoTaq Flexi

Table 4. Materials used for isolation of DNA in pork samples in the southeast of Mexico

Sample	Materials and methods
Isolation of DNA in pork samples (50 grs)	Predigestion whit acid pepsin solution [93]* *Acid pepsin solution (Pepsin 2.6 g; NaCl, 5.0 g; HCl 7.0 mL and distilled water to make 500 ml, pH ~ 1.10-1.20). Phosphate buffered saline (PBS, pH 7.2) Sodium bicarbonate (pH ~ 8.3) Saline solution Blender Plastic jar Layers of gauze Plastic pipettes Follow the protocol for Tissue samples of DNeasy Blood and Tissue Kit (QIAGEN)
General consumables	Pipets and filter tips Vortex Microcentrifuge tubes (1.5mL) Microcentrifuge Centrifuge Thermomixer for heating at 56°C Reagents of DNeasy Blood and Tissue Kit (QIAGEN) Ethanol (96-100%)

Buffer (PROMEGA); 2mM MgCl₂; 0.8 mM dNTPs; 0.5 µM for both the forward and reverse primers; 1.5 U Taq polymerase (GoTaq Flexi DNA Polymerase); and a 2 µL DNA sample in a final volume of 25 µL. The second amplification conditions had the same conditions as the first PCR, except that in this case, the concentration used for the forward and reverse primers was modified to 0.3 µM and as a template for the second round, 2 µL of the product was used from the first round of PCR. The nPCR conditions in the first run were 95°C for 5 min, followed by 30 cycles of 94°C for 30 s, 55°C for 1 min, and 72°C for 2 min. In the second run, the conditions were 95°C for 5 min, followed by 35 cycles of 94°C for 30 s, 60°C for 1 min, and 72°C for 1.5 min. The DNA from *T. gondii* axenic tachyzoite culture was used as a positive control, and a reaction without DNA was used as a negative control in each round of nPCR. The amplification products were observed on 1.5% agarose gel stained with ethidium bromide (10 mg/mL in H₂O).

Protocol for Detection of T. gondii DNA in Pork Samples through a Real Time Quantitative Polymerase Chain Reaction (qPCR)

The primers and Taqman probe amplified a fragment of 62 bp of the B1 gene of *T. gondii*, and the conditions have been previously described [95]. The specific primers used are GENE B1 TG-TX2F(5'-CTAGTATCGTGCGCAATGTG-3') and GENE B1 TG-TX2R(5'-GGCAGCGTCTCTTCCTCTTTT-3') and a TaqMan probe (5'-(6-FAM)-CCACCTCGCC TCTTGG-(NFQ-MGB)-3'). Each qPCR reaction was carried out in a final volume of 25 µL. The reaction conditions were as follow: 1X TaqMan Universal PCR Master Mix (PE Applied Biosystems) at an adjusted MgCl₂ concentration of 5 mM, 0.90 µM of each primer, 0.25 µL of the marker probe and 100 ng of purified DNA from the tissue. The amplification conditions were the following: initial incubation for 2 min at 50°C, followed by 10 min at

95°C, followed by 40 cycles of 95°C for 15 s and 60°C for 1 min. For the absolute quantification of the parasites, serial dilutions (from 1×10^{-2} to 1×10^5 parasites/mL) were performed by duplicated with known amounts of parasites/mL (tachyzoites) to construct the standard curves for *T. gondii* quantification. The parasite load determinations were performed by a linear regression analysis of the Ct values from known amounts of protozoan DNA to determine the *T. gondii* cell equivalents. The parasite load found in each tissue (estimated as a function of the Ct relative position from each sample with the Ct of the standard curve values) was divided per g of the sample to obtain the parasites/g by tissue. The results were expressed as *T. gondii* – equivalents (1 parasite equivalent = 68 femtograms of *T. gondii* DNA).

CONCLUSION

The human population is increasing every day and with it the demand for food of animal origin. Despite the fact that the implementation of intensive systems in the raising of pigs has drastically reduced the prevalence of *T. solium*, *T. gondii* and *T. spiralis* in developed countries, in rural regions of Mexico, it is still common to raise animals in backyard systems. Backyard farming systems are characterized by unhealthy conditions, a lack of confinement facilities, animals with poor diet, and inadequate health care. In addition, these animals are commonly slaughtered in the same homes where they are raised; therefore the rigorous inspection processes for the search of the cysts in their tissues are not carried out with cysts passing from their meat directly to the local consumers. This represents a high risk of infection for the population if this meat is consumed raw or undercooked.

In Mexico, studies of these three parasites *T. solium*, *T. gondii* and *T. spiralis*, in pigs are scarce dated, which makes it difficult to know the current epidemiological status of these agents. Moreover, it is alarming that in the country there are still outbreaks of cysticercosis/taeniasis, toxoplasmosis and trichinosis in the human population, which could indicate that the presence of these parasites in pigs for consumption is being underestimated. The data found in the literature show that these three agents in pork have a high impact on the health of the population; however, their detection is not mandatory. Unfortunately, the raising of backyard pigs is the key to the maintenance of these zoonoses. In addition, until measures are taken to improve production systems, the cycle of *T. solium*, *T. gondii* and *T. spiralis* will continue in the food chain. On the other hand, the breeding tendencies of animals in friendly conditions, free from stress and grazing, have made this parasite reemerge due to the greater exposure of pigs to the contaminated environments.

Prevention measures should be taken when cooking pork carcasses at optimal temperatures (71°C or 160°F) to inactivate the tissue cysts of *T. solium*, *T. gondii* and *T. spiralis* and thus avoid the risk of infection. Other measures for the prevention of these diseases can be contribute to reducing outbreaks in Mexico by increasing the infrastructure in health services in marginalized communities, the implementation of dissemination campaigns regarding the epidemiology of these diseases among communities, and fostering habits of personal hygiene and good practices in breeding of pigs in backyard systems.

Chapter 528

THE LIBERIAN PUBLIC HEALTH SYSTEM

Veronica Fynn Bruey

INTRODUCTION

A brief historical account of Liberia is fundamental to understanding the apparently haphazard approach used to develop a relatively poor public health system in Liberia, which is evidently in need of comprehensive reform after the Ebola virus disease outbreak that occurred between 2014 and 2016. The modern state of Liberia is Africa's oldest republic that was founded by the ACS. The ACS, a philanthropic organisation, was founded in 1816, following the enactment of the *Act Prohibiting Importation of Slaves*, 1807 and the *Act in Addition to an Act to Prohibit the Importation of Slaves*, 1819 by the United States Congress. Liberia was birthed out of the need to address the "problem" of freed slaves being placed on the same legal equality with white people in the United States (Huberich 2010: 18). An amount of \$100,000 was granted to the ACS in 1819 to fund, manage and repatriate the African colonisation (McPherson, 2010: 21). Between 1820 and 1904, some 14,996 Black Africans were removed from the United States to the Colony of Liberia (Brown, 1980: 1; Murdza Jr., 1975: 1; Reef, 2002: 14–18).

Prior to the arrival of African American settler-colonists in 1822 and a Declaration of Independence by African-American former slaves in 1847, the area called Liberia today, was home to a number of indigenous or native groups (Fyfe, 1972:150–152; Korvah, 1995:11). The American Colonisation Society (ACS) claimed to have "purchased" and "bargained" for land from the Natives of Liberia to set up its enclave (Ashmun, 1826: 6). However, evidence of violent conflicts and wars between the ACS and the Natives of Liberia indicates otherwise (Huberich, 2010:278–280). Since the initial dispossession of native Liberians of their lands, African-American settler-colonist elites ruled and controlled Liberia and its natives for well over 133 years (1847-1980) (Dunn und Holsoe, 1985: xiv-xix).

This elite oligarchy of African American in Liberia is mainly responsible for the political unrest observed between 1979 and 1989, which escalated into two full-blown civil wars that lasted for about 14 years (Mgbeoji, 2003: 11–19). Having been "debarred by law from all rights and privileges of men" and forced to economically development a country that gave

them no protection, African American settler-colonists to Liberia sought a land of freedom—“an asylum from the most grinding oppression” (Liberia Declaration of Independence, 1847). But, as the oppressed becomes the oppressor (Freire, 2005: 45), it comes as no surprise what African American settler-colonists did to the native peoples of Liberia. Clinton Caldwell Boone, an African-American missionary-doctor, confirms that, “[t]he civilised Liberian, to maintain his standing as a light and a ruler of the country must live in some way aloof from the people it governs. This is the custom in America and it is far more necessary in Africa” (Boone, 1970: 51). French (2004:91) captures the essence of African American settler-colonists to Liberia:

...the old Americo-Liberian elite – the class of freed American slaves that had founded this country in 1847...settled the land, [and] fondly strove to reproduce the only model they knew, the plantation society of the American South. Affecting top hats and morning coats, the freedmen ruled Africa’s first republic in a clannish and conservative manner, established their own curiously paternalistic brand of apartheid, systematically excluding so-called aborigines from positions of privilege and power until 1980, when a coup by an unschooled soldier and ‘man of the soil’ from the Krahn ethnic group, Master Samuel Kanyon Doe, brought this anachronistic little universe to a bloody end.

It would take decades to comprehend the full extent of the devastating impact and consequences of the Liberian civil wars. Although no accurate statistical account is available, some quantification exists especially regarding the persistent health impact, trauma and burden of disease on Liberia’s public health system. From 1989 to 2003, between 250,000 (United Nations, Security Council 2003: 6) and 270,000 people lost their lives either as a direct result of the wars or due to illness exacerbated by the destruction of health facilities (United Nations Development Program, 2006: 12). During the two civil wars, approximately 800,000 persons were internally displaced (United Nations High Commissioner for Refugees, 2006: 3) and over a million persons became refugees (Nmoma, 1997: 4–5), many of whom are still struggling to return home today (Essuman-Johnson, 2011: 117–119; Genoway, 2018).

The United Nation Mission in Liberia helped to disarm some 103,019 ex-combatants, including 11,282 child soldiers (Agencie Catalan de Cooperacio al Desenvolupament, 2008: 3). It is estimated that a third of Liberians participated in the civil war including ~21,000 child soldiers; but only 28,314 arms, 32,530 ammunition, and 7.1 million small arms ammunition were collected during the Disarmament, Demobilisation and Rehabilitation period which took place between 2003 and 2008 (Agencie Catalan de Cooperacio al Desenvolupament, 2008: 6; Johnson et al., 2012: 531; Paes, 2005: 1; Weiss, 2005: 81). In 2004, a preliminary study conducted by the United Nations Development Program (UNDP) and the National Human Rights Center of Liberia found that 60-70 per cent of Liberians (Amnesty International 2004: 4) suffered some form of sexual violence during the civil conflict.

Against this backdrop, the previous brief discussion of the country’s history provides the context for examining the public healthcare system. Thus, the purpose of this chapter is to examine the Liberian public healthcare system. Specifically, the chapter will discuss some of the major public health laws and policies that have been enacted and implemented, since the founding of the country. Further, the chapter will interrogate the state of the country’s public healthcare system.

PUBLIC HEALTH: CONCEPTS AND PRINCIPLES

Conceptualising Public Health

In his report on Public Health in England, Sir Donald Acheson defines public health as the science and art of preventing disease, prolonging life and promoting health through organized efforts of society (Acheson, 1988: 1). Acheson's definition is both generic and sustainable, drawing on principles of interdisciplinarity, social determinants of health, and the ethics of prolonging life, promoting health and preventing illness. The term population health refers to health outcomes and their distribution in a population (Turnock, 2016: 10). After decades of focusing on treatment as a panacea to ill-health, public health incorporated lifestyle and the environment as serious concerns.

In the early 1990s, John Ashton described the “new public health” approach as one which transcends human biology, combines environmental change and individual preventive measures with appropriate medical interventions, but with focus on vulnerable populations (Ashton 1992: 113). A decade later, Tulchinsky and Varavikova (2010:26) asserted that the new public health is “an integrative approach to protecting and promoting the health status of both the individual and the society.” To this end, it is instructive that contemporary perspectives incorporate socio-economic, political and legal factors into developing and sustaining a robust public health system.

Primary Healthcare

The original definition of primary health care centered on health workers providing medical care to patients on first contact. In 1978, at the International Conference on Primary Health Care in Alma-Ata, the concept of primary health care surpassed medical care on first contact to include social, economic and political factors affecting inequality and poverty (Walt und Vaughan, 1982: 1). The Alma-Ata Declaration IV (1978) states that:

primary health care is essential health care based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self-reliance and self-determination. It forms an integral part both of the country's health system, of which it is the central function and main focus, and of the overall social and economic development of the community. It is the first level of contact of individuals, the family and community with the national health system bringing health care as close as possible to where people live and work, and constitutes the first element of a continuing health care process.

The socio-economic, political and legal effects of health captured by Acheson and the Alma-Ata Declaration are collectively referred to as the social determinants of health. In order to address the social determinants of health, health promotion strategies must be put in place.

Health Promotion

Building on the progress of the Alma-Ata Declaration, the *Ottawa Charter for Health Promotion* was established during the First International Conference on Health Promotion held on November 21, 1986 in Ottawa, Canada. The *Ottawa Charter*, 1986 (the Ottawa Charter) defines health promotion as the process of enabling people to increase control over

and improve their health. The Ottawa Charter also identifies the fundamental conditions required to instil good health: i.e., peace, shelter, education, food, income, a stable ecosystem, sustainable resources, social justice and equity. These fundamental conditions would later form part of the original ten factors Richard Wilkinson and Michael Marmot earmarked as the social determinants of health.

Social Determinants of Health

Social determinants of health are the conditions in which people are born, grow, live, work and age, but are also shaped by the distribution of money, power and resources at global, national and local levels (Wilkinson und Marmot, 2003: 8). These conditions are (but not limited to): social gradient, stress, early life, social exclusion, work, unemployment, social support, addition, food, and transport (Wilkinson und Marmot, 2003: 10–29). Health disparities and inequities are unfair and avoidable differences in health status seen within countries such as Liberia, where the health system is heavily focused on medical care (or secondary and tertiary care).

Although medical care can increase survival and provide cure for some diseases, the population's health is dependent on the social, economic, political and legal conditions that make people ill (Wilkinson und Marmot, 2003: 7). To reduce global health inequalities and improve population health outcomes, WHO established the Commission on Social Determinants of Health between 2005 and 2008. Over the period of three years, the Commission on Social Determinants of Health aimed at and was successful in understanding the social relationships and factors that influenced health and health systems at the national level (Marmot, 2005: 1099).

THE HISTORY OF PUBLIC HEALTH IN LIBERIA

The history of public health in Liberia has a humble beginning with very little evidence to draw on. The first documented material to infer the existence of some sort of a medical or public health initiative in the Colony of Liberia can be found in the *Statute Laws of the Commonwealth of Liberia and Plan of Civil Government*, 1841 (The Statute Laws of the Commonwealth and the Plan for Civil Government, 1841). Under Article VI of the Statute Laws of the Commonwealth, “All Custom, Port, Infirmary, Medical, Guard, and Police Officers [that were] not appointed by the Managers of the Colonisation Society, and whose services are required and defined by the laws of the Colony, together with the public Measurers, Inspectors, and Appraisers, shall be appointed by the Agent of the Colony” (Statute Laws of the Commonwealth of Liberia and the Plan for Civil Government, 1841). Following was the *Act to Provide for the Support and Employment of the Poor*, 1843, which included aged widows, destitute orphans, poor persons and invalid poor (Constitution and Laws of the Commonwealth of Liberia and the Plan for Civil Government, 1841:39-40). In that same year (1841), an *Act Requiring the Register of Births and Deaths*, 1843 (The Birth and Death Act) appointed a Town Clerk to record and report all births and deaths to the Probate Court. Amended to law in 1857, after Liberia declared independence in 1847, saw the

Births and Death Act, which required the Probate Court to submit collected records to the Secretary of State (Constitution and Laws of the Commonwealth of Liberia and the Plan for Civil Government, 1841:30) rather than the Colonial Secretary. Thus, it can be assumed that the newly formed Liberian State did not have a Ministry of Health even ten years after its independence.

In December 1859, *An Act Approving and Appropriating a Certain Amount of Money Assumed and Expended by the President* authorizes the release of \$300 or \$400 dollars from the Public Treasury to assist with preventing the spread of smallpox in Montserrado county (Act of the National Legislature of Liberia, 1859a:50). The Legislature also released an amount of \$200 to Dr. D. R. Fletcher to help minimize smallpox outbreak in Maryland County (Act of the National Legislature of Liberia, 1859b). The first mention of a hospital made by the Liberian Legislature was a resolution passed during the December 1861 session. The resolution authorized the President of Liberia to allocate \$300 annually to St. Mark's Hospital in Harper, Maryland for a term of 10 years (Act of the National Legislature of Liberia, 1861:83). On January 26, 1870, *An Act Incorporating the Palm Grove Cemetery Company of Monrovia* was approved was passed (Act of the National Legislature, 1870). The Palm Grove Cemetery, positioned next to the public burial ground, allow private citizens to purchase plots for burying the dead. The Palm Grove Cemetery Act was the Liberian Government's effort to manage the disposal of dead persons by containing the spread of disease.

In his Third Annual Message of January 23, 1973, President William R. Tolbert, Jr commented on *The Public Health and Safety Law on the Control of Narcotic and Dangerous Drugs*, 1956 (Public Health and Safety Law, 1956). According to President Tolbert, the Public Health and Safety Law was enacted for the purpose of "discharging more effectively the obligation of the Republic under the international conventions to which it is a party" (President Tolbert, 1973)." Violation of sections 406 (Penalty for illegal traffic in drugs), 407 (Penalty for illegal possession of drugs) and 408 (Penalty for other violations) of the Public Health and Safety Law resulted in imprisonment for up to twenty, two and six years, respectively (Dunn, 2011: 1535). While in previous years, the cost of managing the Public Health and Sanitation Bureau was defrayed by loans and introduction of a Public Health and Sanitation tax in 1931, increased revenue for public health from \$0 to \$1,937.35 by 31 July 1932 was observed (Dunn, 2011: 845). In 1950, Liberia's Public Health and Sanitation Bureau appropriated 12 per cent of its total revenue towards Public Health, the highest for any nation apart from Sweden, which expended 15 per cent of its revenues at the time (Dunn 2011: 1145). By 1966, health expenditure rose to \$2.5 million under Tubman's regime (Dunn, 2011: 1360).

Proposal to amalgamate the hospital and sanitary services was first suggested in 1932 under President Edwin J. Barclay (1930-1944) (Dunn, 2011: 845). Dissatisfied with the conditions at the Government Hospital, President Barclay proposed the first Department of Health and Sanitary Service in 1935 in order to maximize efficiency and economic cost of caring for patients (Dunn, 2011: 915). Additionally, a Child and Maternity Health Clinic and a Clinic for the Poor under the auspices of the Bureau of Health and Sanitation were set up in that same year (Dunn, 2011: 915, 928).

PUBLIC HEALTH STATUS AND TRENDS

Statistical data and measurements are an important source of information for law and policy-makers to implement effective public health intervention and engineer social change. The ability numeration has to contextualise a complex and disorganized world is paramount in decision-making processes. In ordering numbers to simplify our world, quantitative data gives a sense of authority, “objective truth and scientific authority” but can be seductive (Merry, 2016: 1). Reliance on indicators with little commitment to systematic study affect power distribution and tilts international health leadership and control towards the West (Davis et al., 2012: 4). Thus, global health statistics should always be interpreted through a critical lens (Merry, 2016: 1–2).

The last census conducted in 2008, put Liberia’s population at 3.5 million (Liberia Institute of Statistics and Geo-Information Services, 2009: 3), although the UNDP projects a current population of 4.5 million people. Liberia ranks relatively low on the Human Development Index at 177 out of 188 countries (United Nations Development Program, 2016: 200). According to the World Health Organisation (WHO), life expectancy for both sexes at birth is 62 years, which increased over 11 years between 2000 and 2012 (World Health Organisation, 2015a: 1). In 2015, Liberia’s health expenditure as percentage of its Gross Domestic Product (GDP) was 15.2 per cent (World Health Organisation, 2017). In concrete terms, for fiscal year 2017/2018, 13.6 per cent (\$77.4 million) of Liberia’s total budget (\$563 million) was spent on health (Government of Liberia, 2017: iii, xv). The highest budget allocation was given to the Public Administration Sector, which received 31.4 per cent (\$176 million) of the total budget for the fiscal year 2017/2018 (Government of Liberia, 2017: xiv). Aid and donor agencies contributed US \$55 million (9.7 per cent) to Liberia’s budget for fiscal year 2017/2018, of which 20 per cent (US \$144 million) was allocated to the Health Sector. In essence, donor and aid agencies spent an excess of US \$ 67 on the health sector compare with that of the Government of Liberia spending on health (Government of Liberia, 2017: xi, 546).

Compounded by the civil war and the Ebola epidemic outbreak, Liberia has seen improvements in under-five mortality rate from a baseline of 248 per 1,000 live births in 1990 to 16 per 1,000 live births in 2016 (UNICEF, 2017: 148). Similarly, maternal mortality ratio has reduced from 1,200 per 100,000 live births to 725 per 100,000 live births (UNICEF, 2017: 179). In spite of the reduction in infant mortality rates and maternal mortality ratios over a 15-year period (World Health Organisation, 2015b: 53), continuous increase in public health access and services between rural and urban areas places Liberia at a relatively high global ranking of 27 out of 192 countries for Infant mortality rate (UNICEF, 2017: 148–149) and 7 out of 181 countries for maternal mortality rate (World Health Organisation, 2015b: 70–77). In effort to address the poor quality of care as a major cause of relatively high maternal and under-five mortality rates, the World Bank launched the *Liberia Health Systems Strengthening* project in 2013. A grant amount of US \$16 million was allotted to support the *Every Woman Every Child* project in Liberia, which focuses on reproductive, maternal, newborn, child and adolescent health (RMNCAH) (World Bank, 2017b: 1–3).

The top ten causes of death in Liberia in 2012 are listed below in Table 1 (World Health Organisation, 2015a). The top three burden of disease affecting disability-adjusted life years

(DALYs) and years of healthy life lost due to disability (YLD)¹ are: human immune-deficiency virus (HIV), tuberculosis (TB), malaria, maternal, neonatal, nutritional and infectious diseases other than acute respiratory diseases, HIV, TB and malaria.

Table 1. Top ten causes of death in Liberia, 2012

Disease/Condition	# of Deaths (000s)	Percentage
Lower respiratory infections	12.2	4.20
Malaria	8.40	2.90
Tuberculosis	5.60	1.90
HIV/AIDS	5.60	1.90
Stroke	5.30	1.80
Diarrhoeal diseases	4.70	1.60
Birth Asphyxia and trauma	4.00	1.40
Ischaemic heart disease	3.50	1.20
Preterm birth complications	3.50	1.20
Maternal conditions	2.90	1.00

Source: Compiled by the Author.

More than 11,400 persons living with HIV in Liberia were enrolled in care with 8,400 actively receiving anti-retroviral therapy (ART) (Gasasira et al., 2016: 20). In 1989, the Ministry of Health's Department of Preventive Services launched the National Leprosy and Tuberculosis Control Program (Ministry of Health, 2014: 1). To this end, tuberculosis notification reduced from 8,132 in 2012 to 5,849 cases in 2015. In 2016, 77 per cent of the 7,119 tuberculosis cases in Liberia were successfully treated (Gasasira et al., 2016: 20). Malaria, endemic in Liberia are the leading cause of attendance at outpatient hospital care (National Malaria Control Program - Liberia et al., 2016: ix), with a national average prevalence rate of 28 per cent (United States Agency for International Development, 2016: 11). To reduce the burden of malaria in Liberia, the Ministry of Health's National Malaria Control Program, in its fourth plan, focuses on scaling up malaria prevention and control (Ministry of Health, Liberia, 2016a: 3). According to WHO, some 1.2 million malaria cases were treated with anti-malaria therapy and approximately 103,892 pregnant women received long lasting insecticidal nets in 2016 (Gasasira et al., 2016: 22–23).

LAW, POLICY AND STRATEGIC PLAN

Ministry of Health and Social Welfare Act 1972 to Ministry of Health Act, 2015

In 1972, the Fourth Regular Session of the Forty-Fifth Legislature of Liberia, repealed *Title 33 of the Liberian Code of Laws*, 1956, entitled: "Public Welfare Law." A new Executive Law, Chapter 30, Title 12, *Liberian Code of Laws, Revised*, 1972 established the Ministry of Health and Social Welfare for the first time (see section 30.1). Duties of the

¹ Disability-adjusted life years (DALYs) are the sum of years of life lost due to premature mortality (YL) and years of healthy life lost due to disability (YLD).

Minister of Health and Social Welfare include the prevention and abatement of conditions hazardous to the public health, *inter alia* (section 30.2 (3)).

In 2015, after 43 years of delivering health service, the Liberian Legislature renamed the Ministry of Health and Social Welfare by passing an *Act to Establish the Ministry of Health, 2015* (Ministry of Health Act), which repealed all social welfare provisions.² The main rationale for separating the “Ministry of Health” from that of “Social Welfare” is to “promote planned and sustainable economic development, efficiency in development resources and effectiveness in the delivery of public services” (preamble, Ministry of Health Act). With a mandate focused on health policy, planning, and delivery standards (section 39.3), the new Ministry of Health moves away from primary care, while emphasizing more on secondary and tertiary care. Albeit, the Department of Preventive Services of the Ministry of Health plans and coordinates prevention activities to control diseases that concern the public’s health, including emergencies, monitoring and outbreaks (Ministry of Health, Liberia, 2018).

The Public Health Law, 1976

The Public Health Law, Title 33, Liberian Code of Laws Revised 1976 (the Public Health Law) was first established in 1956, Title 31. In 1977, an Act of the National Legislature set up the Liberian Association of Public Health Inspectors, now called the Liberian Association of Public Health Technicians. The goal of the Liberian Association of Public Health Technicians was to help implement the Public Health Law by protecting Liberians’ health through preventive health measures (Front Page Africa, 2017). The Public Health Law is divided into seven parts: 1) General Provisions, 2) Control of Acute Communicable Diseases and Conditions, 3) Environmental Sanitation, 4) Health Standards of Public and Private Institutions, 5) Regulation of Drugs, 6) Vital Statistics: Disposal of Human Remains, and 7) Regulation and Supervision of Medical and Allied Health Professions. Though considered elaborate at the time, the Public Health Law provides no definition of Public Health and is silent on non-communicable diseases, mental health, or public health emergency preparedness.

Chapter 14.2 of the Public Health Law, invests power in the Minister of Health to make rules regarding a cadre of matters, including but not limited to, 1) conducting house visitation (Chapter 14.2 (b)); 2) preventing any person from leaving an infected area without undergoing medical examination (Chapter 14.2 (d)); 3) establishing hospital and observation camps or stations (Chapter 14.2 (e)); 4) removal of person with the disease and those in contact with such persons (Chapter 14.2 (g)); and 5) removal of corpses (Chapter 14.2 (h)). As indicated above, amidst the Ebola Virus outbreak in 2014, former President Sirleaf asserted that the Public Health Law was inadequate to handle the Ebola epidemic holistically and comprehensively (Johnson-Sirleaf, 2014). Thus, in its current state, the Public Health Law makes no provision for handling public health emergencies whether through quarantine or through other monitoring or surveillance measures (Public Health Law, 1956)³

² Chapter 39, Executive Law, Title 12, Liberian Code of Laws, Revised, 2015

³ Chapter 11(i) and (k) of the Public Health Law defines isolation and quarantine as it pertains the “Control of acute communicable diseases and conditions”. These terms are not used anywhere in Chapter 14: Formidable Epidemic, Endemic or Infectious Diseases.

The Public Health Law criminalises “risky” behaviours and practices. For instance, Chapter 14.6 of the Public Health Act states: “Any person other than a public officer who violates any of the provisions of this chapter or any of the rules made thereunder shall, upon conviction, be liable to a fine not exceeding two hundred dollars or to imprisonment not exceeding thirty days, or to both such fine and imprisonment.” The Public Health Law is further critiqued for being very general and incongruent to the health realities at the time (World Health Organisation, 2005), yet heavily focused on regulating drugs, standards for health workers, and licensing of health professionals. Much needed revision of the Public Health Law started in 2011 with assistance from Jeannette Austin (another individual foreign to the Liberian health system), serving with a team of in country lawyers in developing a new public health law (Austin, 2011).

Ministry of Gender and Development Act, 2001

As noted above, the “Social Welfare” aspects of the old Ministry of Health and Social Welfare is now moved to the Ministry of Gender, Children and Social Protection, formerly known as the Ministry of Gender and Development. Back in 1998, under the leadership of former President Charles Ghankay Taylor, Grace Minor, then Senator of Montserrado County and Chairperson of the Senate Standing Committee on Executive called for the establishment of a Ministry of Gender Affairs in Liberia. Senator’s Minor’s recommendation for establishing a Ministry of Gender was apt then as Liberia was barely recovering from the scourge of its first civil war, which predisposed many girls and women to violence and abuse. The proposed Ministry of Gender Affairs was to “seek the enhancement and protection of women rights...” as women have been marginalised for so long in Liberia and therefore needed to be “educated massively of their rights and roles in this male dominated Liberian society” (Staff Reporter, 1998). In 2001, *An Act to Amend the Executive Law Title 12 (The Gender and Development Act)*, established the Ministry of Gender.

In 2013, overlap between the responsibilities of the Ministry of Health and Social Welfare and that of the Ministry of Gender and Development regarding care of children, led to the Governance Commission’s Bill.⁴ On April 8, 2014, the 53rd Legislature of Liberia amended Chapter 38 of the New Executive to establish the Ministry of Gender, Children and Social Protection (Staff Reporter, 2014a). All functions and powers of the repealed social welfare provisions of the old Ministry of Health and Social Welfare is now transferred to the new Ministry of Gender, Children and Social Protection (Cabran, 2014: 12). Grounded in population health approach by focusing on health outcomes, determinants, policy and intervention of group of individuals (Kindig and Stoddart, 2003: 380), the Ministry of Gender, Children and Social Development mandate is to

promote the development, empowerment and protection of women, girls and children, as well as the welfare and integration of persons with disabilities, the vulnerable, extremely poor, excluded and disadvantaged. Specifically, the Ministry will initiate, develop and implement and/or coordinate policies and programs aimed at women, girls, and children, as well as those physically challenged, marginalised, disadvantaged and excluded, to ensure that their rights are protected and that they are integrated, and contribute

⁴ An Act to Amend Chapter 38 Ministry of Gender and Development, of the Executive Law, to Establish the Ministry of Gender, Children and Social Protection, 2013

to, and benefit from, the peace, stability and socio-economic advancement of the country (Section 38.3, *Ministry of Gender, Children and Social Development Act*, 2014).

Interestingly, the Ministry of Gender, Children and Social Protection has no Department of Social Welfare included in its organisational structure (Cabran, 2014: 12).

Section 7 (e) of the *Ministry of Gender, Children and Social Protection Act*, 2013 transfers all assets, personnel, and remaining budget from the Ministry of Health and Social Welfare's Department of Social Welfare to the Ministry of Gender, Children and Social Protection. The Ministry of Gender, Children and Social Protection leads with mainstreaming government-wide efforts to ensure gender equality and empowerment of women and development of children. The Ministry of Gender, Children and Social Protection is the driving force behind the enforcement of the Universal Declaration of Human Rights, *Convention on the Elimination of All Forms of Discrimination against Women (CEDAW)*, 1989 the Convention on the Rights of the Child, the *Protocol to the African Charter on the Human and Peoples' Rights on the Rights of Women in Africa*, 2003 the African Children's Charter, and the United Nations Security Council 1325 on Women Peace and Security. The roles of both the Ministries of Health and Gender are significantly increasing in the lives of children and women in post-war Liberia (Fuest 2008), especially with the new addition of social protection of children.

Basic Package of Health Services, 2008

The first government health insurance program, the "Hospitalisation Insurance Plan," was introduced in 1936 under the presidency of Barclay where paying a premium of 50 or 60 cents per month entitled a person to free hospital treatment over a specified period (Dunn, 2011: 915). In recent times, with assistance from international donor agencies, the Government of Liberia is gradually moving towards establishing national health coverage program that would expand the population access to public health care. The Basic Package of Health and Social Welfare Services, 2008 (the Basic Package of Health), founded on the fundamental principles of primary health care and decentralisation of health services management; targets maternal, child, adolescent, reproductive, mental health, communicable disease control and emergency care. The main objectives of the Basic Package of Health are to: 1) standardise the service delivery package at the five levels of the Liberian health system; and 2) redistribute essential health services to ensure universal access throughout Liberia (Government of Liberia, 2008: 1–3).

While the goals of the Basic Package of Health appear to be doable, Roberts et al., argue that disruption in care and fragmented health service delivery caused by damaged infrastructure, limited human resources, weak stewardship and proliferation of non-governmental organisations are common symptoms of countries, such as Liberia, emerging from violent conflict (Roberts et al., 2008). Enhancing the implementation of the Basic Package of Health hinges on the idea of continuous assessment. Accreditation is one way to conduct continuous assessment of the Basic Package Health programs as it does not only improve quality of care, but it also facilitates monitoring of trends and evaluation of health systems. While successful accreditation systems have existed in high- and middle-income

countries, many low-income countries such as Liberia, have fallen behind in establishing effective health facilities programs (Cleveland et al., 2011: 272).

For instance, in 2007, the Ministry of Health and Social Welfare did not have basic information about health care in Liberia. With assistance from the Clinton Foundation, a Basic Package of Health Service accreditation program was initiated amidst extreme logistical and implementation challenges (Cleveland et al., 2011: 272). In particular, the Basic Package of Health was designed to track quality improvement or measure of quality of care. Nevertheless, the accreditation program allowed the Ministry of Health to gather unprecedented amounts of information about the current status of service provision across the country, well beyond directly tracking and measuring quality of care (Cleveland et al., 2011: 275).

Mainly due the Ebola Virus Disease epidemic (Kruk et al., 2017), the Government of Liberia mobilised to develop another policy to improve public health intervention programs. Emphasising the fact that health workers experienced a 30 times higher risk of infection compared as to the general population, (i.e., as of 8 April 2015, 372 healthcare workers were infected and 184 had died), *the Investment Plan for Building a Resilient Health System* emerged in 2015 with assistance from the World Bank Group (Ministry of Health and Social Welfare 2015; 2017a). Like the National Health Policy and Plan, the Investment Plan for Building a Resilient Health System (Government of Liberia, 2015: iii and 1) aims to provide universal access to safe and quality services through improved capacity of the health network for provision of safe, quality Essential Packages of Health Services, as well as a robust Health Emergency Risk Management System through building public health capacity for prevention, preparedness, alert and response for disease outbreaks and other health threats. In spite of the aforementioned, a study conducted in 2008 with 1,405 individuals in Nimba country, found that rural communities in Liberia still have limited access to life-saving health care (Kruk et al., 2010: 527).

National Health Policy Plan, 2011

The first-ever National Health and Social Welfare Financing Policy and Plan was established in 2007 to supervise and standardize the finances to implement the National Health and Social Welfare Policy and Plan, 2011–2021 (Ministry of Health and Social Welfare, 2006: 13, 2011: 5). Recognizing that health and social welfare are key determinants of human development, and in the context of national social and economic growth strategy, then Ministry of Health and Social Welfare led the development of one holistic National Health and Social Welfare Policy and Plan, 2011–2021 (Government of Liberia, 2011: 6) with the aim of substantially improving the health and social welfare of Liberia's population health.

Mental Health Act, 2017

Consistent with the National Health Policy and Basic Package of Health, the National Mental Health Policy, 2010 was Liberia's first major attempt to address mental health

problems comprehensively and incorporate it into all areas of health and health delivery service (Ministry of Health and Social Welfare, 2010: 10). In the past, mental illness in Liberia was exclusively limited to severe forms of psychotic disorders treated by traditional and religious leaders who saw the disease as one of witchcraft or demonic possession (Ministry of Health and Social Welfare, 2010: 14). Even after the Catherine Mills Rehabilitation Center was established in the 1960s, mental health patients still roamed the streets of Liberia commonly referred to as “crazy people.” The Catherine Mills Rehabilitation Center, the only psychiatric care facility in the country, was destroyed during the civil war (Ballah, 2016c) but now has 75 beds and provide care for both in- and out-patients (Ministry of Health and Social Welfare, 2010: 14).

In 2016, the Ministry of Health released a new 5-year Mental Health Policy and Strategic Plan for Liberia, 2016-2021 (Mental Health Policy, 2016) that will expand access to mental health clinicians and develop new Wellness Units in every county (Ministry of Health, 2016b: v). Drawing on the Basic Package of Health and the Investment Plan for Building a Resilient Health System 2015-2021, the Mental Health Policy, 2016 emphasizes on secondary and tertiary care. Though, two primary care strategic objective of the Mental Health Policy, 2016 are: 1) sensitize communities about mental health and illness and modify, 2) encourage families of persons with neuropsychiatric disorders to be involved in the care and management of their loved ones (Ministry of Health and Social Welfare, 2010: vi).

Prior to 2017, Liberia had only one psychiatrist (Massachusetts General Hospital, 2018) and no mental health law for protecting its estimated 300,000 persons suffering from mental illnesses (Cooper, 2017) and many more survivors of the 14-year civil war. Now, the country boasts of four psychiatrists and 230 mental health personnel (Cooper, 2017), in addition to enacting a mental health law. On May 23, 2017, the Liberian Legislature unanimously amended the Public Health Law by adding Part VIII, Health and Related Rights, Chapter 2, Mental Health (Ballah, 2017; Sonpon, 2017). On November 30, 2017, the Carter Center in Liberia reported that the Mental Health Act handbill was released and distributed by the Ministry of Foreign Affairs, an indication of the official enactment of “Liberia’s first law to improve health care for people with mental illnesses and prevent discrimination against them” (Cooper, 2017). The new Mental Health Act aims to

provide for and protect the civil, social and health rights of all persons with mental disorders and/or mental disabilities including persons with intellectual disabilities; promotes and regulates equitable and effective access to timely, appropriate and quality mental healthcare, treatment, habilitation and rehabilitation for all persons in the 15 counties, including those with mental disorders and/or mental disabilities; establish and enforce the responsibilities and obligations of the government in carrying out the duties set forth (Sonpon, 2017).

Children’s Act, 2011

Signatory to the *Universal Declaration of Human Rights* (UDHR), 1948; the *Convention on the Rights of the Child* (CRC), 1989; the African Charter on the Rights and Welfare of the Child (the African Children’s Charter), 1990; and the *Convention on the Elimination of All Forms of Discrimination against Women* (CEDAW), 1979; Liberia legislated *An Act to Establish the Children’s Law of Liberia* (the Children’s Law), 2011. According to the United Nations Children’s Fund (UNICEF), “Liberia is one of the first countries to adopt

comprehensive legislation for children that incorporates the UNCRC and the African Charter” (Pradhan, 2012). The Children’s Act covers a broad range of rights and protection that generally speaks to primary care approach of children’s health. Section 8, Article III, of the Children’s Act particularly deals with the right to access medically necessary health care, while Article VII focuses on children’s situations of vulnerability. In spite of progress made with the establishment of the Children’s Law, the vulnerability and risk to ill-health of Liberian are many.

Although there has been some progress with reducing infant and under mortality rates in Liberia as indicated above, a relatively high maternal mortality rate implies that many children die with their mothers inside the womb (UNICEF-Liberia, 2018). Liberia ranks second highest in the first global primary out-of-school rate at 62 per cent of children out of school (UNESCO Institute for Statistics, 2017: 6). Out of school of many children implies increased vulnerability to neglect, violence, abuse and exploitation. According to the United States Department of Labor, Liberian children are engaged in some of the worse forms of child labor including, being trafficked and exploited for commercial sex, forced domestic work, forced begging and performing dangerous tasks in the production of rubber, mining gold and diamonds (Bureau of International Labor Affairs, 2016: 1–2).

National Commission on Disabilities Act, 2005

In 2005, the Liberian Legislature enacted *the National Commission on Disabilities Act* 2005, with a mandate to deal with the general welfare and education of persons with disabilities in Liberia (Swedish International Development Cooperation 2014: 4). Following the set-up of the National Commission on Disability, Liberia signed (March 30, 2007) and ratified (July 26, 2012) the *United Nations Convention on the Rights of Persons with Disabilities*, 2006⁵ (United Nations 2018). The National Commission on Disabilities is an autonomous agency having “*jurisdiction over all matters involving and appertaining to general welfare, wellbeing, education of all disabled persons within the Republic of Liberia.*”⁶ Section 7 of the Act, authorized the Government of Liberia to make budgetary appropriation for the education, social and economic development of all disabled persons within minutes of passing the National Commission on Disabilities Act. Despite its overzealous aspiration, the National Commission on Disabilities continues to struggle (Tamba, 2018). In an address by President Johnson Sirleaf to the National Union of Organisations of the Disabled, the National President, Reverend Fallah S. Boima discloses that,

...the [National Union of Organisations of the Disabled], which is the mother organisation of all disabled persons in Liberia, does not have a stable source of funding to support its activities and programs... That the subsidy provided by government through the National Commission on Disabilities cannot cover the monthly rent of the Union’s office and it stands to be evicted from its office shortly (Executive Mansion, 2015).

⁵ On 30 March 2007, Liberia signed the Optional Protocol to the Convention on the Rights of Persons with Disabilities, 2006 but has not ratified yet.

⁶ Section 2, National Commission on Disabilities Act.

Statistical data on persons with disabilities in Liberia is non-existent. Albeit, a study carried out by the Center for Rehabilitation of the Injured and disabled in 1997 found that 16 per cent of the Liberian population live with a disability (UNICEF-Liberia, 2012: 15). According to a report by the Swedish International Development Agency, approximately 20 per cent (or 800,000 persons) have disability in Liberia as a direct result of the civil war (Swedish International Development Cooperation, 2014: 1). One can only imagine the situation of people with disabilities living in remote Liberia when its centralised location in Monrovia is already at risk for being “homeless” due to lack of funding and budgetary allocation (Swedish International Development Cooperation, 2014: 4). In its National Human Rights Action Plan of Liberia, 2013-2018; the government of Liberia stated two major objectives regarding the rights of persons with disabilities and other vulnerable groups (Government of Liberia, 2013: 23–24):

1. Improve accessibility to disability-specific services and reduce stigmatisation and discrimination against all vulnerable groups; promote their right to be treated equally.
2. Improve protection for marginalised and vulnerable groups at all levels of the administration of justice (police, prison system, courts) and marginalised groups within society and strengthen capacity for response, referral and follow-up of gender-specific issues.

Whether full and comprehensive implementation of the above objectives will be materialised by the end of 2018, is a matter of time, effort and commitment on the part of the government to carry out an evaluation of the human rights action plan. The law, policies and strategic plans listed above promise to create an enabling environment that restores trust in the health authorities’ ability to provide national public health services and delivery through community engagement grounded in leadership, effective governance and accountability at all levels.

PUBLIC HEALTH PROGRAM: SERVICE, INSTITUTION AND TRAINING

Health Facilities and Services

The Government of Liberia has always supported and funded national health initiatives by establishing public health institutions to provide services to its population. In 1943 and 1948, \$37,623.68 and \$248,077, respectively were allocated to the Bureau of Public Health and Sanitation to be used towards health care of 44,647 patients across 15 health centers⁷ across the country (Dunn, 2011: 1088). In 1949, the Bureau of Public Health and Sanitation engaged in swamps drainage program in efforts to combat malaria outside of the City of Monrovia (Dunn, 2011: 1112). In that same year (1949), either a hospital, clinic or special sanitary works were established in Cape Mount, Grand Bassa, Sinoe, Cape Palmas, Webbo, Tchien, Tappita, Sannequellie, Gbarnga, Salala, River Cess, Timbo, Maryland, Voinjama, Bopulu and Clay-Ashland (Dunn, 2011: 1112).

⁷ Monrovia, Bassa, Voinjama, Cape Palmas, Tchien, Tappita, Webbo, Sinoe, Cape Mount, Salala, Crozierville, Gbarnga, River Cess, Marshall and Bopulu Health Centers.

On May 3, 1972, the Liberian Legislature approved an act to create the John F. Kennedy Medical Center (JFK Medical Center) as an autonomous agency of the Government of Liberia.⁸ The JFK Medical Center comprised the John F. Kennedy Memorial Hospital, Maternity Hospital, the Tubman National Institute of Medical Arts (a paramedical and nursing school), and the Catherine Mills Rehabilitation Hospital. Now also repealed (i.e., the JFK Medical Center Act, 1972) the main goal of the JFK Medical Center was to provide medical care to the population of Liberia and serve as a center of training in the medical, paramedical and public health fields.⁹ As such, the JFK Medical Center currently serves as a tertiary health care facility, the main national referral center primary and secondary healthcare, as well as, the teaching hospital for the A. M. Dogliotti School of Medicine (Government of Liberia, 2017: 231).

Table 2. Showing Percentage of Health Access, Public Health Facilities and Health Workers in the 15 Counties of Liberia, 2008

#	County	Population	Access to Healthcare (%)	Public Hospitals	Health Clinics	Doctors	Registered Nurses
1	Grand Bassa	182,937	NA	2	31	0	0
2	Bomi	105,345	<15	1	15	1	10

The purpose of the newly enacted *John F. Kennedy Memorial Center Act*, 2013 (JFK Memorial Center) is to provide specialist care and services, conduct training programs for health professionals as a teaching hospital, and promote health-related scientific research (Staff Reporter, 2014a). Heavily focused on treatment, cure, and teaching, the JFK Memorial Center does not have a Public Health Division, which attest to the struggle it faced during the Ebola epidemic outbreak. After 46 years of its existence (1972-2018), the historically public-run national hospital, is barely equipped with basic X-rays, emergency room, surgical capabilities, laboratory services provided by very few specialists, and allied health care providers. Although one of two national tertiary care facilities in the country, the JFK Medical Care Center accepts only cash payment from patients. In 2016, Daylue Goah,

⁸ *An Act to Amend the Executive Law to Create the John F. Kennedy Medical Center*, 1972, Government Printing Office Ministry of Foreign Affairs, Monrovia, 6 May 1972.

⁹ Preamble of *An Act to Amend the Executive Law to Create the John F. Kennedy Medical Center*, 1972

formally employed as a Public Relation Officer of the JFK Memorial Center, alleged ongoing corruption and poor services specifically regarding senior staff members stealing donated medication and delivering treatment that resulted in patients' death (Dweh 2016). Daylue's accusation of corruption was recently confirmed by the General Auditing Commission (Dodoo, 2018). In response, Dr. Wannie Scott-McDonald, Head of the JFK Memorial Center, enumerated achievements under her leadership, including staff training, renovations, increase in staff salary and constant supply of medication to patient (Rogers, 2016). That being said, a most recent media report highlighted the breakdown of the largest public health center in Liberia due to budget cuts (Senkpen, 2018). Compiled from individual County Development Agendas released in 2008, Table 2 (below) shows a glimpse of health facilities, practitioners and basis services provided across Liberia.

Health Professionals, Education and Training

Historically, Liberia has struggled with training qualified health personnel as the Country has only one public health school (privately owned), and a medical and a nursing school that is publicly funded. As early as 1948, Liberian health professionals were sponsored by foreign governments. For example, the United States Government sponsored Dr. Joseph N. Togba, Chief of the Bureau of Health and Sanitation, who took up a special post-graduate course in public health and sanitation in the United States in 1948 (Dunn, 2011: 1088). In cases where there were insufficient qualified health practitioners, the Government of Liberia sought the assistance of foreign nationals, a practice still existing today (Staff Reporter, 2018a). For example, in 1949, former President William V. S. Tubman recruited nine doctors from Germany, adding to the already eight government doctors to help increase the number of medical doctors for the growing population of Liberia (Dunn, 2011: 1113). There are a number of private institutions providing health, nursing, and public health education and training. However, the challenge most Liberians face is the ability to afford the cost of attending public health schools and finding a job after completing their educational programs. To date, no PhD programs are offer in Liberia, as such, the conduct of high quality research in Liberia is constrained by many factors, making it difficult to produce and access scholarly resource materials.

Tubman National Institute of Medical Arts

The Tubman National Institute of Medical Arts furthers educational, health and social development in Liberia by training health workers for the rural areas. The Tubman National Institute of Medical Arts was established in 1945 in collaboration with the Liberian National Public Health Services and the United States Mission in Liberia. In 1964, as the need to established a physician assistant program for the development of health workers for the rural areas arose, the Government of Liberia in collaboration with WHO and UNICEF, establish the a two-year training physician assistant program which was later increased to three years in 1976 (Kennedy, 2011). To date, the Tubman National Institute of Medical Arts operates four programs: School of Environmental Health, School of Midwifery, School of Physician Assistant and School of Professional Nursing (Kennedy, 2011). It has graduated over 3000 para-medical health workers as of 2013 (Kennedy, 2011), although not without challenges

(All Africa, 2013; Wolokolie, 2013). However, recent “investment into trained midwives” across the country brings hope for improvement (WHO, 2016) with the launching of the new University of Liberia Nursing School. Until 2014, the Tubman National Institute of Medical Arts was the only publicly funding nursing program in the Country (Staff Reporter, 2014b). In September 2015, the University of Liberia, in collaboration with the JFK Medical Center and the Tubman National Institute of Medical Arts commenced a four-year Bachelor in Nursing and Midwifery with 19 students enrolled (Staff Reporter, 2015).

A. M. Dogliotti Medical School at the University of Liberia

In 1966, then President William V. S. Tubman, with assistance from the Italian Government, the Vatican and the Achille Mario Dogliotti Foundation, established the Monrovia-Torino Medical School in hopes of training medical doctors for Liberia as well as Africa at large (AM Dogliotti College of Medicine, 2010: 3). Initially affiliated with the Faculty of Medicine and Surgery of the University of Turin in Italy, in 1970 the Monrovia-Torino Medical School merged with the University of Liberia and was renamed Achille Mario Dogliotti College of Medicine, becoming the second professional school in Liberia (A. M. Dogliotti College of Medicine 2010: 3). After the inauguration of the John F. Kennedy Memorial Hospital in 1971, the Achille Mario Dogliotti College of Medicine became the teaching hospital of A. M. Dogliotti College of Medicine. From its opening in 1966 until 2009, the A. M. Dogliotti College of Medicine graduated 273 doctors (Executive Mansion, 2009).

A situational and observational report of A. M. Dogliotti College of Medicine highlighted its rickety and neglectful state, noting broken down structures with no access to running water, electricity, or internet (Nyan, 2006). Notwithstanding, in 2016, enrollment at the AM Dogliotti College of Medicine included 231 medical students, 79 pharmacy students, and 20 students in nursing and midwifery (Ballah, 2016b). As not much has changed today (Ballah 2016b), the question remains whether Liberia will ever be prepared for a future epidemic in the face of the lingering possibility of the resurgence of the Ebola Virus Disease.

Cuttington University's Master of Public Health Program

Named in honor of Robert Fulton, Cuttington's Treasurer of the Board of Missions of the Episcopal Church in the United States, the Old Cuttington Collegiate and Divinity School (the Old Cuttington) was founded in 1889, in Cape Palmas, Liberia (Cuttington University, 2018b). At the time, enrollment was limited to only 100 students, all of whom were only men. Due to financial challenges, the Old Cuttington was closed down in 1929 (Cuttington University, 2018b). Re-named, Cuttington College and Divinity School and with guidance from Bishop Bravid W. Harris, then Bishop of Liberia, the New Cuttington opened in 1949 as a co-educational Liberal Arts College (Cuttington University, 2018b). Renamed again in 1977, Cuttington University College, made up of six degree granting colleges, moved to Suakoko, Bong County, on 1,500 acres of rich agricultural land that was donated to the Episcopal Church by the Government of Liberia during the presidency of William V. S. Tubman (Cuttington University, 2018b). A fully accredited university in Liberia, Cuttington University now has seven colleges that offer 13 degrees and 8 certificates in its undergraduate programs, including a Bachelor of Nursing, and offers 11 graduate degrees, including a Master of Nursing Administration, and a Master of Public Health (MPH) (Cuttington University, 2018a).

Located in Oldest Congo Town on Tubman Boulevard in Monrovia, Cuttington University's Department of Community Health offers the MPH degree, and accommodates students with background in natural sciences, health sciences, sociology and other related disciplines (Cuttington University, 2017: 53). The vision of Cuttington University's MPH program is "[t]o train and qualify graduates in Community Health capable of using evidence-based problem-solving approach in dealing with some of the many complex and vexing public health and related issues challenging Liberia and the world at large" (Cuttington University, 2017: 53–54).

ADDRESSING PUBLIC HEALTH EMERGENCY

The government of Liberia first allocated funds to address the outbreak of smallpox in the 1861.¹⁰ Two outbreaks of smallpox in Grand Cape Mount County and the Central Province in 1935, prompted former President Edwin J. Barclay to appoint Dr. Kreuger and Dr. Jung as Medical Officer of Health and Supervisor of the Sanitary Work in both the Western Province and Grand Cape Mount Country, respectively (Dunn, 2011: 908). Dr. Anigstein, an Expert of Tropical Medicine, from the University of Warsaw, was also appointed to advise the Government on matters of sanitation and public health (Dunn, 2011: 908–909). To this end, the Government of Liberia was successful in arresting 186 cases of smallpox and vaccinating 26,427 persons, which rose to 70,177 over a two year period (Dunn, 2011: 908, 914). By 1937, a mild epidemic of Influenza hit the Montserrado area, in addition to 236 cases of smallpox infection sparking the vaccination of 109,950 persons over a period of eight months (Dunn, 2011: 928). Along similar lines, three Leprosy stations we set up across the country to reduce forcible isolation of lepers (Dunn, 2011: 908, 914–915).

In recent times, the Ebola Virus Disease pandemic in West Africa created a new public health challenge never seen before in Liberia. Before the outbreak of the Ebola Virus epidemic in August 2014, Liberia was already stricken by poverty, corruption, hunger and civil war. Growth and development in Liberia was stunted by a 14-year civil war. After the civil war officially ended in 2003, the country's estimated population of 4.1 million was served by 50 licensed Liberian-trained doctors, now upgraded to 298 for 4.5 million people in 2016 (Ballah 2016a: 1) and 437 health facilities as at 2008 (Black et al., 2016: 292). By May 11, 2016, WHO reported 10,666 cases and 4,806 deaths of the Ebola Virus disease in Liberia with a case fatality rate of 72.3 per cent for persons between the ages of 15 and 44 years with a known clinical outcome of the infection (World Health Organisation, 2016).

At the peak of the Ebola crises, former President Ellen Johnson Sirleaf, declared a State of Emergency on August 6, 2014, affirming that public health emergency response measures pursuant to the Public Health Act were inadequate to handle the Ebola epidemic holistically and comprehensively (Johnson-Sirleaf, 2014). To this end, President Sirleaf imposed extraordinary measures, including the suspension of certain rights and privileges of citizens in order to address the Ebola outbreak, which at the time had no cure with a 90 per cent fatality rate. Additionally, then Ministry of Health and Social Welfare released Regulations by the Minister of Health (the "Minister") Governing the Control and Abatement of the Spread and Eradication of the Ebola Virus Disease (EVD) in Liberia (The Anti-Ebola Regulation), 2014.

¹⁰ An Act Passed During the December 1859 Session of the National Legislature of Liberia.

Applied throughout Liberia, the Anti-Ebola Regulation emphasized the duty of local health authority to pick-up, transfer and isolate persons suspected or symptomatic of the Ebola Virus Disease as well as several methods to prevent spread of the disease.¹¹ Since the Ebola Virus epidemic, the Government of Liberia has initiated efforts to build and strengthen a resilient health system in preparing for public health emergency and improving the population's health. Herewith are two key examples:

Integrated Disease Surveillance and Response

In 2006, the Ministry of Health (MOH) adapted a generic integrated disease surveillance and response (IDSR) in collaboration with the World Health Organisation-Regional Office for Africa (AFRO) and the United States Centers for Disease Control and Prevention (CDC) in Atlanta (Centers for Disease Control and Prevention, 2017). The IDSR framework implements the International Health Regulations to effectively respond to severe emergency outbreaks of mostly preventable diseases (Centers for Disease Control and Prevention, 2017). Frimpong et al., (2017:9). suggest that early detection, reporting and response to public health events help to reduce the burden of mortality and morbidity on communities. Therefore, careful analysis of reliable surveillance data is required to implement timely and appropriate public health interventions (Frimpong et al., 2017: 6). For Liberia, sustaining and strengthening a resilient health system is dependent on the collection of high quality IDSR data on both communicable and non-communicable diseases (Ministry of Health, Liberia et al., 2016: 18).

National Public Health Institute of Liberia

In 1967, President Tubman instituted a National Public Health Service, an advisory council on health with the following terms of reference: The Council advised the Chief Executive on all aspects of clinical and preventive medicines and dentistry, including advice on the development, organisation and administrative practice of public health and clinical programs over a 10-year period (Dunn, 2011: 1267).

Decades after the establishment of the National Public Health Service, followed by unprecedented loss of 4,806 lives during the Ebola Virus Disease, Liberia will establish another national public health institution. In January 2017, the National Public Health Institute of Liberia (the National Public Health Institute) was established (Staff Reporter, 2018b; The International Association of National Health Institutes, 2016) with a mission to “prevent and control public health threats by promoting healthy outcomes and serving as a source of knowledge and expertise” (National Public Health Institute of Liberia 2018). In collaboration with the Ministry of Health, the National Public Health Institute also helps to strengthen prevention, surveillance and control of infectious diseases by building public health capacity in responding to outbreaks and monitoring potential epidemic (National Public Health Institute of Liberia, 2018). Since the Ebola epidemic in Liberia, the National Public Health Institute, in partnership with WHO, releases the IDSR Weekly Epidemiology and Surveillance Bulletin (National Public Health Institute of Liberia, 2016).

¹¹ Regulations by the Minister of Health (the “Minister”) Governing the Control and Abatement of the Spread and Eradication of the Ebola Virus Disease (EVD) in Liberia, hereinafter, The Anti-Ebola Regulation (MoHSW/R-001/2014). See, sections 1, 2, 3, 4 and 7.

CONCLUSION

The lack of research and access to resource presented a real challenge in writing this chapter on the Liberian Public Health System. Notwithstanding the limited resources available on public health in Liberia, the chapter demonstrates over and again that the Liberian public health system is not only ad hoc but in dire need of reform, especially regarding access to care in the rural communities. The Government of Liberia's ongoing struggle to develop and maintain functioning health facilities, supply qualified healthcare workers and allocate adequate budgetary funding for public health is a clear reflection of the extremely poor public health system in the country.

Irrespective of some progress made with establishing relevant public health law, policy, strategic plans, institutions and preventive measures after the Ebola Virus Disease epidemic; Liberia still has a long way to go in implementing a resilient and sustainable public health system for the well-being of all Liberians, including vulnerable populations such as women, children and people with disability. It can only be hoped that the newly established Ministry of Health, Ministry of Gender, Children and Social Protection and the National Public Health Institution will combine forces to augment the population health of Liberia within a timely fashion.

Chapter 529

OPIOID CRISIS: STATUS OF PUBLIC HEALTH EMERGENCY AUTHORITIES*

United States Government Accountability Office

Opioid misuse and related deaths are a serious, growing public health problem in the United States. According to the Department of Health and Human Services' (HHS) Centers for Disease Control and Prevention (CDC), over 42,000 people died from opioid-involved overdoses in 2016. The federal government has launched a number of initiatives to combat the opioid crisis, and HHS issued a five-point Opioid Strategy in April 2017 to guide the department's efforts.¹ We and others have reported on ongoing federal actions to address opioid issues.²

On October 26, 2017, the Acting Secretary of HHS declared the opioid crisis a public health emergency under section 319 of the Public Health Service Act and the declaration was renewed in January, April, and July 2018.³ A public health emergency triggers the availability of certain authorities under federal law that enable federal agencies to take actions such as accessing the Public Health Emergency Fund, temporarily reassigning certain state and local

* This is an edited, reformatted and augmented version of the United States Government Accountability Office Report to the Congressional Requesters, Publication No. GAO-18-685R, dated September 26, 2018.

¹ The Opioid Strategy's five priority areas are: 1) better access to prevention, treatment, and recovery services; 2) better data on the epidemic; 3) better pain management; 4) better targeting of overdose-reversing drugs; and 5) better research on pain and addiction.

² See, for example, GAO, Prescription Opioids: Medicare Needs Better Information to Reduce the Risk of Harm to Beneficiaries, GAO-18-585T (Washington D.C.: May 29, 2018); Illicit Opioids: While Greater Attention Given to Combating Synthetic Opioids, Agencies Need to Better Assess their Efforts, GAO-18-205 (Washington, D.C.: March 29, 2018); Opioid Use Disorders: HHS Needs Measures to Assess the Effectiveness of Efforts to Expand Access to Medication-Assisted Treatment, GAO-18-44 (Washington, D.C.: Oct. 31, 2017); Newborn Health: Federal Action Needed to Address Neonatal Abstinence Syndrome, GAO-18-32 (Washington D.C.: Oct. 4, 2017); and Prescription Opioids: Medicare Needs to Expand Oversight Efforts to Reduce the Risk of Harm, GAO-18-15, (Washington D.C.: Oct. 6, 2017).

³ A declaration is in effect until the Secretary declares the emergency no longer exists, or 90 days after the declaration, whichever occurs first. A declaration that expires may be renewed by the Secretary. The then-Acting Secretary made the determination for the October 2017 public health emergency declaration for the opioid crisis and the January 2018 renewal of this declaration. The current Secretary made the determination for the April and July 2018 renewals of the declaration.

personnel, and waiving certain administrative requirements. These authorities may allow the federal government to increase support to and reduce administrative burdens on state and local governments and federal grantees affected by or responding to the public health emergency. They may also supplement other federal efforts that are ongoing to address the emergency. While the Secretary of HHS may declare a public health emergency, the use of some authorities requires coordination with other agencies, including the Department of Justice (Justice) and the Department of Labor (Labor). The October 2017 declaration was the first time that a public health emergency declaration was made for the opioid crisis. Public health emergencies have previously been declared for infectious disease outbreaks, such as the Zika and the H1N1 influenza virus outbreaks, as well as for hurricanes and other weather events.⁴

You asked us to review the decision to declare a public health emergency for the opioid crisis, and what actions have been taken under the declaration. In this report, we describe:

1. the factors HHS indicated as affecting its decision to declare and renew the public health emergency for the opioid crisis, and
2. the public health emergency authorities the federal government has used to address the opioid crisis.

To address these objectives, we reviewed relevant HHS statements and decision documents and interviewed HHS officials about the basis for declaring a public health emergency for the opioid crisis. These officials included those from the Substance Abuse and Mental Health Services Administration (SAMHSA), the agency within HHS that leads public health efforts focused on reducing the negative effects of substance abuse and mental illness. In addition, we reviewed the Public Health Service Act and related statutory and regulatory provisions to identify the authorities that become available during a public health emergency. We also reviewed HHS, Labor, and Justice documents and interviewed agency officials to determine which of the available authorities have been used and their status, including reasons that some authorities were not used. In addition, we reviewed information from HHS about other recently declared federal public health emergencies where these authorities were last used. This report focuses on public health emergency authorities and does not examine other federal efforts to combat the opioid crisis.

We conducted this performance audit from March 2018 to September 2018 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

⁴ See GAO, *Emerging Infectious Diseases: Actions Needed to Address the Challenges of Responding to Zika Virus Disease Outbreaks*, GAO-17-445 (Washington, D.C.: May 23, 2017) and *Influenza Pandemic: Lessons from the H1N1 Pandemic Should be Incorporated into Future Planning*, GAO-11-632 (Washington, D.C.: June 27, 2011).

RESULTS IN BRIEF

Increasing rates of opioid-related deaths and opioid use disorder were the primary factors for the declaration of a public health emergency for the opioid crisis on October 26, 2017, and for its renewal on January 19, 2018, according to HHS officials. Officials cited still-increasing rates of opioid-related deaths in 2017 for the declaration's renewal on April 20, 2018, as well as the consideration that a nationwide public health emergency underscores the urgency of ongoing federal, state, and local efforts to combat the opioid crisis. More recently in July, HHS again renewed the declaration due to the continued consequences of the opioid crisis.

Since declaring the opioid crisis a public health emergency, the federal government has used three available authorities. According to HHS officials, one of them allowed HHS to quickly field a survey of more than 13,000 providers to assess prescribing trends for a medication used to treat opioid use disorder and any barriers to prescribing it. HHS used another authority to waive the public notice period for approval of two state Medicaid demonstration projects related to substance use disorder treatment, which is intended to speed up implementation of these projects. HHS also took steps to expedite support for research on opioid use disorder treatments and to disseminate information on opioid misuse and addiction, as required by another authority. In addition to these 3 authorities, we identified 14 other authorities that became available as a result of the public health emergency and have not been used.⁵ According to HHS officials, these additional authorities have not been used for a variety of reasons: for example, HHS officials determined that many are not relevant to the circumstances presented by the opioid crisis. Officials told us they will continue to review the authorities as the opioid crisis evolves and in the context of HHS's other efforts to address the opioid crisis.

BACKGROUND

Opioids, such as hydrocodone, oxycodone, morphine, and methadone, can be prescribed to treat both acute and chronic pain. Because many opioids have a high potential for abuse and may lead to severe psychological or physical dependence, many of them are classified as Schedule II drugs under the Controlled Substances Act.⁶ The misuse of opioids has been associated with serious consequences, including addiction, overdose, and death. Recently, there has been a rise in opioid use in the United States involving both the misuse of prescription drugs and illicit opioids, such as heroin.

The federal government has taken certain actions to address the crisis. For example, we reported on efforts by HHS to expand access to medication-assisted treatment for those who

⁵ We identified authorities that become available as a result of a public health emergency declaration under section 319 of the Public Health Service Act, as well as other authorities that become available when there is a public health emergency, but that do not require a declaration. For the purposes of this report, we refer to these authorities collectively as authorities triggered by a public health emergency.

⁶ Under the Controlled Substance Act, which was enacted in 1970, drugs are classified as controlled substances and placed into one of five schedules based on their currently accepted medical use, potential for abuse, and risk of dependence.

misuse or are addicted to opioids—a condition known as opioid use disorder.⁷ Medication-assisted treatment, which combines behavioral therapy and the use of certain medications (methadone, buprenorphine, and naltrexone), has been shown to reduce opioid use and to increase treatment retention compared with abstinence-based treatment, where patients are treated without medication.⁸ We also recently reported on federal efforts to combat synthetic opioids, such as by limiting their availability and expanding prevention programs and treatment options.⁹ Synthetic opioids, including fentanyl, often have very high potency that can increase the risk of overdose.

In March 2017, the President issued Executive Order 13784 establishing a commission to study the scope and effectiveness of the federal response to drug addiction and the opioid crisis.¹⁰ The President's Commission on Combating Addiction and the Opioid Crisis issued a final report in November 2017, making a number of recommendations to the President to enhance the federal government's response to the opioid problem. Further, on October 26, 2017, the President directed the Acting Secretary of HHS to declare the opioid crisis to be a public health emergency.

Under section 319 of the Public Health Service Act, the Secretary of HHS may declare a public health emergency if the Secretary determines, in consultation with other public health officials as may be necessary, that (1) a disease or disorder presents a public health emergency; or (2) a public health emergency, including significant outbreaks of infectious disease or bioterrorist attacks, otherwise exists.¹¹ Section 319 does not specify any additional requirements or procedures that the Secretary must follow to declare a public health emergency. Under section 319, the Secretary of HHS can take appropriate action in response to a public health emergency, including making grants, providing awards for expenses, entering into contracts, and conducting and supporting investigations into the cause, treatment, or prevention of the underlying disease or disorder. In addition, section 319 includes specific authorities that can be used for such things as extending deadlines for any report required to be submitted under any law administered by HHS and temporary reassignment of state and local personnel whose positions are funded, at least in part, under programs authorized under the Public Health Service Act. Public health emergency declarations also trigger the availability of other authorities outside of section 319. In addition, other authorities may become available when there is a public health emergency but do not require a declaration. The use of these authorities in previous public health emergencies has varied, and some authorities have not been used. Enclosure I lists the authorities available when there is a public health emergency.

⁷ GAO-18-44.

⁸ Methadone and buprenorphine suppress withdrawal symptoms in detoxification therapy and control the craving for opioids in maintenance therapy. Both drugs are opioids that activate opioid receptors and carry risks of misuse. Both drugs can also be used to treat pain. Naltrexone is used for relapse prevention because it suppresses the euphoric effects of opioids, and it carries no known risk of misuse.

⁹ GAO-18-205.

¹⁰ Executive Order No. 13784 of March 29, 2017, 82 Fed. Reg. 16,283 (Apr. 3, 2017).

¹¹ Distinct from a public health emergency declaration are two declarations available to the President under the Robert T. Stafford Disaster Relief and Emergency Assistance Act (Stafford Act): a major disaster declaration and an emergency declaration. The President can issue either type of declaration under the Stafford Act at the request of the governor of an affected state or a chief executive of an affected Indian Tribe. The President may also declare a national emergency under the National Emergencies Act, which authorizes the President to activate existing emergency authorities in other statutes. The President did not make these declarations for the opioid crisis.

The federal government has declared public health emergencies for infectious disease outbreaks, such as the Zika and the H1N1 influenza virus outbreaks, and for hurricanes, such as Hurricane Maria in Puerto Rico, and for other weather-related events. Enclosure II lists other recent public health emergencies.

HHS Officials Cited Increasing Rates of Opioid-Related Deaths and Opioid Use Disorder as Primary Factors for Declaring and Renewing the Public Health Emergency

According to HHS officials, the primary factors for declaring and renewing the public health emergency for the opioid crisis were the increasing rates of opioid-related overdose deaths and opioid use disorder, especially the increase in overdoses as a result of synthetic opioids such as fentanyl.¹² The public health emergency for the opioid crisis was first declared on October 26, 2017, by the Acting Secretary of HHS, who also renewed the declaration in January 2018.¹³ In April 2018, SAMHSA recommended that the Secretary of HHS again renew the public health emergency declaration for the opioid crisis, noting specifically the provisional 2017 estimates from CDC indicating that opioid-related overdose deaths continued to increase in 2017.¹⁴ In addition, SAMHSA's April recommendation cited a March 2018 CDC report stating that emergency department visits due to opioid overdoses—a measure of opioid-related morbidity—had increased significantly in the past year, increasing almost 30 percent from the third quarter (July through September) of 2016 to the third quarter of 2017.¹⁵ In particular, among approximately 91 million emergency department visits captured from July 2016 through September 2017 in the National Syndromic Surveillance Program, a total of 142,557 (15.7 per 10,000 visits) were suspected opioid overdoses.¹⁶ HHS officials told us that in addition to CDC's provisional estimates for opioid-related mortality and the emergency department visit data on suspected opioid-related overdoses, HHS relied on multiple other data sources to inform the public health burden of the opioid crisis.¹⁷

SAMHSA officials noted that the existence of a nationwide public health emergency has spurred additional action across HHS and underscores the urgency of federal, state, and local efforts to combat the opioid crisis, many of which were ongoing prior to the declaration, such as efforts to expand access to medication-assisted treatment. Further, SAMHSA stated that

¹² Synthetic opioids are man-made opioids, such as fentanyl and fentanyl analogues. An analogue is a drug molecule that shares structural similarities with the original compound. It may also share pharmacological similarities. For more information about synthetic opioids and federal agencies' efforts to combat them, see GAO, *Illicit Opioids: Office of National Drug Control Policy and Other Agencies Need to Better Assess Strategic Efforts*, GAO-18-569T (Washington D.C.: May 17, 2018), and GAO-18-205.

¹³ This renewal was declared on January 19, 2018, and effective January 24, 2018.

¹⁴ This renewal was declared on April 20, 2018, and effective April 24, 2018.

¹⁵ Vivolo-Kantor, A.M., Seth, P., Gladden, R.M., et al. "Vital Signs: Trends in Emergency Department Visits for Suspected Opioid Overdoses — United States, July 2016–September 2017." *Morbidity and Mortality Weekly Report* vol. 67:279–285 (2018).

¹⁶ The National Syndromic Surveillance Program promotes the development of a syndromic surveillance system for the timely exchange of syndromic data. Syndromic surveillance uses syndromic data and statistical tools to detect and monitor unusual activity for further public health investigation or response. Syndromic data include patient encounter data from emergency departments, urgent care, ambulatory care, and inpatient healthcare settings, as well as pharmacy and laboratory data. These data are monitored in near real-time as potential indicators of an event, a disease, or an outbreak of public health significance.

¹⁷ The additional data included, among others, data on opioid misuse and use disorder from SAMHSA's National Survey on Drug Use and Health, rising rates of injection drug use among treatment admissions reported into SAMHSA's Treatment Episode Data Set, the Agency for Healthcare Research and Quality's Healthcare Costs and Utilization Project hospitalization and emergency department data, and CDC's data on rising rates of hepatitis C.

renewing the public health emergency declaration provided HHS additional time to consider how the public health emergency authorities might be used to supplement ongoing federal efforts. More recently, the Secretary of HHS again renewed the declaration on July 19, 2018, and stated that the renewal was due to the continued consequences of the opioid crisis.¹⁸

The Federal Government Has Used Three Public Health Emergency Authorities to Help Address the Opioid Crisis

Since declaring the opioid crisis a public health emergency, the federal government has used three public health emergency authorities to help address the crisis, as of July 2018. Specifically, these are:

- *Waiver of Paperwork Reduction Act requirements.* This authority allows the Secretary of HHS to waive requirements under the Paperwork Reduction Act for the voluntary collection of information when necessary to prepare for and respond to a public health emergency.¹⁹ HHS officials told us that, by using this authority, they were quickly able to field a critical survey of more than 13,000 providers to assess prescribing trends of a medication, buprenorphine, used to treat opioid use disorder and any barriers to prescribing it. According to officials, they were able to streamline the survey review process, including bypassing a review by the Office of Management and Budget that is typically required, which allowed HHS officials to deploy the survey in March 2018 and collect more current data in a much shorter timeframe than they would have without the authority. As of April 2018, officials reported receiving over 5,000 responses. Officials told us the results of the survey will inform policy and programmatic decisions related to increasing access to substance abuse treatment.
- *Waiver of public notice procedures for section 1115 Medicaid demonstrations.* This authority allows HHS's Centers for Medicare & Medicaid Services (CMS) to waive federal and state public notice procedures to expedite a decision on a proposed Medicaid section 1115 demonstration project that addresses a public health emergency.²⁰ These demonstrations allow states to test and evaluate new approaches for delivering Medicaid services.²¹ Generally, after receipt of an application from a state to begin or extend a demonstration, CMS must provide for a 30-day public comment period and wait at least 45 days before making a final decision.²² HHS

¹⁸ This renewal was declared on July 19, 2018, and effective July 23, 2018.

¹⁹ The Paperwork Reduction Act was enacted, in part, to minimize the burden for individuals, small businesses, and others resulting from the collection of information by or for the federal government. Among other things, the Act requires federal agencies to justify any collection of information from the public by establishing the need for and intended use of the information, estimating the burden that the collection will impose on the respondents, and showing that the collection is the least burdensome way to gather the information. Paperwork Reduction Act of 1995, Pub. L. No. 104-13, 109 Stat. 163 (1995).

²⁰ Medicaid is a joint federal-state program that finances health care coverage for low-income and medically needy populations. Section 1115(a) of the Social Security Act allows the Secretary of HHS to waive certain federal Medicaid requirements and allow federal funding for items and services that would not otherwise be eligible for federal funding for experimental, pilot, or demonstration projects that, in the Secretary's judgment, are likely to promote Medicaid objectives. The Secretary has delegated the approval and administration of Medicaid section 1115 demonstrations to CMS.

²¹ GAO, *Medicaid Demonstrations: Evaluations Yielded Limited Results, Underscoring Need for Changes to Federal Policies and Procedures*, GAO-18-220, (Washington, D.C.: Jan. 19, 2018).

²² See 42 C.F.R. §§ 431.416(b) and (e) (2017).

officials reported that they waived the public notice requirements for two states—Louisiana and New Hampshire in February 2018 and July 2018, respectively—for the submission of demonstration applications related to substance use disorder treatment.

- *Expedited support for research.* When a public health emergency is in effect, the Secretary of HHS, acting through the Director of the National Institutes of Health (NIH), is required under one of the authorities to take steps to expedite support for research on the disease or disorder underlying the public health emergency and disseminate information on the cause, prevention, and treatment of the disease or disorder.²³ In December 2017, NIH announced expedited procedures for research funding on medication development for opioid use disorder and overdoses. In addition, according to HHS officials, NIH is disseminating information on opioid misuse and addiction through a website about the research goals and funding opportunities of its Helping to End Addiction Long-term (HEAL) initiative, launched in April 2018, and by updating related publications.

In addition to these 3 authorities, we identified 14 other authorities available under a public health emergency. As of July 2018, these 14 authorities have not been used under the public health emergency declaration for the opioid crisis. HHS officials provided reasons for why they were not using these authorities, and we categorized these reasons in table 1 below. (See enclosure I for a list of the 17 available authorities, the source and description of each authority, the reasons agency officials provided for why some authorities were not used during the public health emergency for the opioid crisis, and the last public health emergency declaration during which agency officials identified using the authority.)

Table 1. Reasons cited by agency officials that certain public health emergency authorities have not been used for the opioid crisis, as of July 2018

Reason authorities were not used	Number of authorities
Officials determined authority was not relevant to the opioid crisis; more appropriate to a short, time-limited public health issue or when infrastructure is damaged	5
Officials reported that no eligible entities, such as states, requested the use of this authority	3
Officials determined that other authorities could be used, rather than public health emergency authorities	3a
Officials expressed concerns that use of authority could increase the risk of diversion of medications for improper use	2a
Officials determined authority was not applicable because dependent upon use of the Public Health Emergency Fund, which has not been used	1
Officials determined that the statutory conditions for using the authority have not been met	1

Source: GAO analysis of information from Department of Health and Human Services, Department of Justice, and Department of Labor. | GAO-18-685R.

^a One of the authorities is listed under two reasons.

²³ Health Research Extension Act of 1985, Pub. L. No. 99-158, 99 Stat. 820 (codified as amended at 42 U.S.C. § 289c).

Examples of the authorities, and the reasons that agency officials provided for why they have not been used, include the following:

- **Access to National Dislocated Worker Grants.** This authority allows the Secretary of Labor to award grants to states or other local areas that have been impacted by emergencies, disasters, or major economic dislocations. These grants provide funding to create temporary employment opportunities to assist with clean-up and recovery efforts, among other things. Labor officials reported that no eligible entities have submitted applications for these grants during the public health emergency for the opioid crisis, as of July 2018.²⁴ Officials noted that a number of factors might have affected why potential grantees have not submitted applications for these grants, including that another grant option is available—the National Health Emergency Dislocated Worker Demonstration Grants—which was established to help communities address the economic and workforce-related impacts of the opioid crisis.²⁵
- **Application extensions and waiver of requirements for block grant funding.** This authority allows the Secretary of HHS to provide an application extension for or waive compliance with requirements for mental health and substance abuse block grant funding during a public health emergency.²⁶ HHS officials told us this provision is not relevant to the public health emergency for the opioid crisis, as it is generally used when a local or state health department building is destroyed by a natural disaster, such as an earthquake or hurricane, and grant data is lost.²⁷
- **Modifications to the practice of telemedicine.** During a public health emergency, this authority allows the Secretary of HHS, with concurrence of the Attorney General, to reduce restrictions on the use of telemedicine when prescribing controlled substances, including those used in the treatment of opioid use disorder.²⁸ HHS officials stated that they have not used this authority because federal law provides for other circumstances under which these restrictions do not apply, thereby allowing the use of telemedicine. Officials also expressed concerns about increasing the risk of diversion of medications for improper use and maintaining high quality of care.²⁹
- **Access to the Public Health Emergency Fund.** The Secretary of HHS may access the Public Health Emergency Fund to take action to respond to a public health emergency, including making grants, providing awards for expenses, and entering

²⁴ The National Dislocated Worker Grant authority was last used in September 2016 while the public health emergency declaration for the Zika virus in Puerto Rico was in effect. On September 28, 2016, Labor awarded a \$6 million National Dislocated Worker Grant to the Puerto Rico Department of Labor and Human Resources, to employ temporary workers to assist with recovery efforts to address the Zika outbreak.

²⁵ In July 2018, Labor announced more than \$22 million in National Health Emergency Dislocated Worker Demonstration Grant funding to six state grantees. The grants will be used to provide reemployment services for individuals impacted by the health and economic effects of widespread opioid use, addiction, and overdose.

²⁶ This authority specifically applies to grants for assistance in transition from homelessness, grants for community mental health services, and grants for the prevention and treatment of substance abuse during a public health emergency.

²⁷ As of July 2018, HHS officials reported that they have never used this authority during a public health emergency.

²⁸ Telemedicine generally refers to the use of electronic information and telecommunications technologies to support long-distance health care through technologies such as videoconferencing.

²⁹ As of July 2018, HHS officials told us that they have never used this authority during a public health emergency.

into contracts for conducting and supporting investigations into the cause, treatment, or prevention of the disease or disorder presenting a public health emergency. According to documents provided by HHS, the Public Health Emergency Fund has a balance of about \$57,000. According to HHS officials, HHS has not requested that Congress appropriate money to the Fund for the current public health emergency and, instead, has used other sources of federal funds to address the opioid crisis.³⁰

HHS officials told us they will continue to assess the relevancy of these and other authorities as the opioid overuse issue evolves across the country, in the context of HHS's other efforts to address the opioid crisis.

Agency Comments

We provided a draft of this report to HHS, Labor, and Justice for comment. HHS and Labor provided technical comments, which we incorporated as appropriate. Justice told us that they did not have any comments.

* * *

As agreed with your offices, unless you publicly announce the contents of this report earlier, we plan no further distribution until 30 days from the report date. At that time, we will send copies of this report to the Secretary of Health and Human Services, the Secretary of Labor, the Attorney General, and appropriate congressional committees. In addition, the report will be available at no charge on the GAO website at <http://www.gao.gov>.

If you or your staff have any questions concerning this report, please contact me at (202) 512- 7114 or DeniganMacauleyM@gao.gov. Contact points for our Offices of Congressional Relations and Public Affairs may be found on the last page of this report. GAO staff who made key contributions to this report were Will Simerl (Assistant Director), Natalie Herzog (Analyst-in-Charge), Amy Andresen, Kaitlin M. Farquharson, Laurie Pachter, and Carmen Rivera-Lowitt.

Sincerely yours,

Mary Denigan-Macauley
Acting Director,
Health Care

Enclosure(s) – 2

³⁰ HHS officials reported that the Public Health Emergency Fund was last used in 1993 for the Hantavirus outbreak. The Public Health Emergency Fund, established in 1983, is available to the Secretary of HHS without fiscal year limitation to take appropriate action in response to a public health emergency. See Pub. L. No. 98-49, 97 Stat. 245 (1983).

Enclosure I: Public Health Emergency Authorities

A public health emergency triggers the availability of certain authorities under federal law. These authorities may allow the federal government to increase support to and reduce administrative burdens on state and local governments and federal grantees affected by or responding to the public health emergency. We identified authorities that become available as a result of a public health emergency declaration under section 319 of the Public Health Service Act, as well as other authorities that become available when there is a public health emergency but do not require a declaration. Table 2 lists the public health emergency authorities; the source of the authority; a description of the authority; the reason an authority was not used during the public health emergency for the opioid crisis as of July 2018, according to Department of Health and Human Services and Department of Labor officials; and the last public health emergency declaration during which agency officials identified using the authority.

Table 2. List of federal public health emergency authorities and description of their use under the opioid crisis public health declaration and other public health emergency declarations

Authority	Description
Funding-related authorities	
Access to funds in the Public Health Emergency Fund	•Authority: Pub. L. No. 98-49 (1983) (codified as amended at 42 U.S.C. § 247d(a) and (b)) •Description: This provision allows the Secretary of Health and Human Services to take appropriate action to respond to a public health emergency, including by making grants, providing awards for expenses, entering into contracts, and conducting and supporting investigations into the cause, treatment, or prevention of the disease or disorder. The Secretary may access the Public Health Emergency Fund to carry out these functions if the Secretary has declared a public health emergency. Appropriations made to the Public Health Emergency Fund are available to the Secretary without fiscal year limitation. Such funds may be used to supplement and not supplant other federal, state, and local public funds.

Table 2. (Continued)

Authority	Description
Funding-related authorities	
	•Reason not used for opioid public health emergency: Department of Health and Human Services (HHS) officials determined that other authorities could be used, rather than public health emergency authorities. HHS also provided evidence that the Public Health Emergency Fund currently contains approximately \$57,000. •Last use during a public health emergency: According to. HHS officials, this authority was last used to respond to an outbreak of Hantavirus in 1993
Supplies and services in lieu of award funds	•Authority: Public Health Security and Bioterrorism Preparedness and Response Act of 2002, Pub. L. No. 107-188, § 110 (codified at 42 U.S.C. § 247d-7c) •Description: This provision allows the Secretary of HHS to provide supplies, equipment, services, and HHS personnel to help an award recipient, at the recipient's request, carry out the purposes of the award. The Secretary is required to reduce award payments by an amount equal to the value of the supplies, equipment, services, and personnel. •Reason not used for opioid public health emergency: HHS officials determined this authority is not applicable because it is dependent upon the use of the Public Health Emergency Fund. Specifically, this authority applies to awards under 42 U.S.C. §§ 247d through 247d-7b and 247d-7d. •Last use during a public health emergency: According to HHS officials, this authority has never been used for awards from the Public Health Emergency Fund.
Waiver of certain Ryan White HIV/AIDS program requirements	•Authority: Ryan White HIV/AIDS Treatment Modernization Act of 2006, Pub. L. No. 109-415, § 501 (codified at 42 U.S.C. § 300ff-83) •Description: This provision allows the Secretary of HHS to waive requirements under Title XXVI of the Public Health Service Act, the Ryan White HIV/AIDS Program, to improve the health and safety of those receiving care under the Program and the general public in an area and during a period in which there exists: (1) a public health emergency declared by the Secretary under section 319 of the Public Health Service Act or (2) an emergency or disaster declared by the President under the Robert T. Stafford Disaster Relief and Emergency Assistance Act or the National Emergencies Act. The Secretary may not spend more than five percent of supplemental funds available under each of the Parts A and B to ensure access to care during a public health emergency. •Reason not used for opioid public health emergency: HHS officials reported that no eligible entities, such as states, requested the use of this authority. •Last use during a public health emergency: This authority was last used during the public health emergency declared for Hurricanes Irma and Maria in September 2017.
Access to National Dislocated Worker Grants	•Authority: Workforce Innovation and Opportunity Act, Pub. L. No. 113-128, § 170 (2014) (codified at 29 U.S.C. § 3225) •Description: This provision allows the Secretary of the Department of Labor (Labor) to award grants to eligible entities to provide employment and training assistance to workers in emergency or disaster areas and to those affected by major economic dislocations. Eligible entities may include states and entities capable of responding to the emergency, disaster, or dislocation. Eligible entities may apply for grants in the event of (1) an emergency or major disaster, as defined in the Robert T. Stafford Disaster Relief and Emergency Assistance Act, or (2) an emergency or disaster of national significance that could result in a potentially large loss of employment, as declared by the chief official of a federal agency with jurisdiction over the federal response to the emergency or disaster. •Reason not used for opioid public health emergency: Labor officials reported that no eligible entities, such as states, requested the use of this authority. •Last use during a public health emergency: This authority was last used during the public health emergency declared for the Zika virus outbreak in August 2016.
Medication-related authorities	
Modifications to the practice of telemedicine	•Authority: Ryan Haight Online Pharmacy Consumer Protection Act of 2008, Pub. L. No. 110-425, § 3 (codified at 21 U.S.C. § 802(54)(D)) •Description: The Ryan Haight Online Pharmacy Consumer Protection Act of 2008 generally requires a health care practitioner to have conducted at least one in-person exam prior to prescribing a controlled substance. This provision allows the Secretary of HHS, with the concurrence of the Attorney General, to designate patients located in certain areas and

Authority	Description
Funding-related authorities	
	controlled substances that are excepted from the in-person exam requirement during a public health emergency declared by the Secretary under section 319 of the Public Health Service Act. •Reason not used for opioid public health emergency: HHS determined that other authorities could be used, rather than public health emergency authorities and HHS officials expressed concerns that use of authority could increase the risk of diversion of medications for improper use. •Last use during a public health emergency: According to HHS officials, this authority has never been used.
Exemption from certain drug distribution supply chain requirements	•Authority: Drug Quality and Security Act, Pub. L. No. 113-54, § 202 (2013) (codified at 21 U.S.C. §§ 353(e)(4)(C), 360eee, and 360eee-1(a)(3)) •Description: The Drug Supply Chain Security Act, enacted as Title II of the Drug Quality and Security Act, generally establishes requirements for drug manufacturers, repackagers, wholesale distributors, and dispensers to facilitate the tracing of prescription drugs through the supply chain. Upon a public health emergency declaration under section 319 of the Public Health Service Act, prescription drugs distributed for the public health emergency are excluded from the Act's product tracing and wholesale distribution requirements, including those pertaining to wholesale distribution. In addition, section 360eee-1(a)(3) requires the Secretary of HHS to establish, by guidance, a process for requesting a waiver from these and other requirements related to product tracing and wholesale distribution for emergency medical reasons, such as a public health emergency declaration under section 319 of the Public Health Service Act. •Reason not used for opioid public health emergency: HHS officials expressed concerns that use of authority could increase the risk of diversion of medications for improper use. •Last use during a public health emergency: According to HHS officials, certain Drug Quality and Security Act emergency authorities were last used during the public health emergency declared for Hurricane Maria in September 2017.
Adjustment of Medicare reimbursement for certain Part B drugs	•Authority: Medicare Prescription Drug, Improvement, and Modernization Act of 2003, Pub.L. No. 108-173, § 303 (codified at 42 U.S.C. § 1395w-3a(e)) •Description: This provision allows the Secretary of HHS to pay the wholesale acquisition cost or other reasonable measure of price instead of the manufacturer's average sales price for a Medicare Part B-covered drug during a public health emergency declaration under section 319 of the Public Health Service Act. These drugs are typically administered under a physician's supervision and include injectable drugs, some oral cancer drugs, and drugs infused or inhaled through durable medical equipment. To exercise this authority, there must be a documented inability to access a drug or biological and a concomitant price increase that is not reflected in the manufacturer's average sales price for one or more quarters. •Reason not used for opioid public health emergency: HHS determined that the statutory requirements for an alternative payment methodology have not been met. •Last use during a public health emergency: According to HHS officials, this authority has never been used.
Research-related authorities	
Research related to public health emergencies ^a	•Authority: Health Research Extension Act of 1985, Pub. L. No. 99-158, § 2 (codified as amended at 42 U.S.C. § 289c) •Description: If the Secretary of HHS determines that a disease or disorder constitutes a public health emergency, this provision requires the Secretary of HHS, acting through the Director of NIH, to (1) expedite review by advisory councils and peer review groups of applications for grant research on the disease or disorder; (2) exercise authority to waive advertising requirements for contract proposals for research on the disease or disorder; and (3) disseminate information to health professionals and the public on the cause, prevention, and treatment of the disease or disorder that has been developed
	through this research. The Secretary may also provide administrative supplemental increases in existing grants and contracts to support new research relevant to the disease or disorder. •Reason not used for opioid public health emergency: Not applicable, because the authority was used. •Last use during a public health emergency: This authority was last used during the public health emergency declared for the opioid crisis in October 2017.

Table 2. (Continued)

Authority	Description
Funding-related authorities	
Temporary reassignment of state and local personnel	•Authority: Pandemic and All-Hazards Preparedness Reauthorization Act of 2013, Pub. L. No. 113-5, § 201 (codified at 42 U.S.C. § 247d(e)) •Description: This provision allows the Secretary of HHS to authorize the temporary reassignment of federally-funded state and local public health department or agency personnel funded under programs authorized under the Public Health Service Act, for purposes of addressing a public health emergency in a state or tribe. The reassignment must occur at the request of a state governor or tribal organization and may not exceed the period of a public health emergency declaration under section 319 of the Public Health Service Act. •Reason not used for opioid public health emergency: HHS officials reported that no eligible entities, such as states, requested the use of this authority. •Last use during a public health emergency: According to HHS officials, this authority has never been used.
Temporary (up to one year or the duration of the emergency) appointments of personnel	•Authority: 5 C.F.R. § 213.3102(i)(3) (2017) •Description: Under this authority, the Secretary of HHS is allowed to make temporary (up to one year or the duration of the emergency) appointments of personnel to positions that directly respond to a public health emergency when the urgency of filling positions prohibits examining applicants through the competitive process. •Reason not used for opioid public health emergency: HHS officials determined that other authorities could be used, rather than public health emergency authorities. •Last use during a public health emergency: This authority was last used during the public health emergency declared for Hurricanes Irma and Harvey in September 2017.
Activation of the National Disaster Medical System (NDMS) ^a	•Authority: Public Health Security and Bioterrorism Preparedness Response Act of 2002, Pub. L. No. 107-188, § 102 (codified as amended at 42 U.S.C. § 300hh-11(a)(3)) •Description: NDMS is a coordinated effort between federal, state, and private entities to respond to public health emergencies. This provision allows the Secretary of HHS to activate NDMS to provide health services, health-related social services, other appropriate human services, and appropriate auxiliary services to respond to the needs of victims of a public health emergency, whether or not a public health emergency declaration under section 319 of the Public Health Service Act has been made. HHS may also activate NDMS in a location that is at-risk of a public health emergency. •Reason not used for opioid public health emergency: HHS officials determined not relevant to the opioid crisis; more appropriate to a short, time-limited public health issue or when infrastructure is damaged. •Last use during a public health emergency: This authority was last used during the public health emergency declared for Hurricanes Irma and Maria in September 2017.
Deployment of the Volunteer Medical Reserve Corps ^a	•Authority: Pandemic and All-Hazards Preparedness Act, Pub. L. No. 109-417, § 303 (2006) (codified at 42 U.S.C. § 300hh-15(e)) •Description: The Secretary is required to build on state, local, and tribal programs to establish and maintain a Volunteer Medical Reserve Corps to provide an adequate supply of volunteers during a public health emergency. This provision allows the Secretary of HHS to activate and deploy willing members of the Volunteer Medical Reserve Corps to areas of need during a public health emergency, taking into consideration the public health and medical expertise required, with the concurrence of the state, local, or tribal officials from the area where the members reside. •Reason not used for opioid public health emergency: HHS officials determined not relevant to the opioid crisis; more appropriate to a short, time-limited public health issue or when infrastructure is damaged. •Last use during a public health emergency: HHS officials did not provide information on when this authority was last used.

Authority	Description
Funding-related authorities	
Deployment of Commissioned Corps Officers ^a	•Authority: Pandemic and All-Hazards Preparedness Act, Pub. L. No. 109-417, § 206(c)(1) (2006) (codified at 42 U.S.C. § 215(e)) •Description: This provision allows the Secretary of HHS to deploy any Commissioned Corps officer to an entity outside of HHS for service under the Secretary's direction in response to an urgent or emergency public health care need. For purposes of this provision, an "urgent or emergency public health care need" includes a health care need arising as a result of (1) a national emergency declared by the President under the National Emergencies Act; (2) an emergency or major disaster declared by the President under the Robert T. Stafford Disaster Relief and Emergency Assistance Act; (3) a public health emergency declared by the Secretary under section 319 of the Public Health Service Act; or (4) any emergency that, in the Secretary's judgment, is appropriate for deployment. •Reason not used for opioid public health emergency: HHS officials determined not relevant to the opioid crisis; more appropriate to a short, time-limited public health issue or when infrastructure is damaged. •Last use during a public health emergency: This authority was last used during the public health emergency declared for Hurricanes Irma and Maria in September 2017.
Paperwork-related authorities	
Waiver of requirements under the Paperwork Reduction Act	•Authority: 21st Century Cures Act, Pub. L. No. 114-255, § 3087 (2016) (codified at 42 U.S.C. § 247d(f)) •Description: This provision allows the Secretary of HHS to waive requirements under the Paperwork Reduction Act for voluntary collection of information when necessary to prepare for and respond to a public health emergency. To exercise this authority, the Secretary must determine (1) that the criteria for a public health emergency have been met or that a disease or disorder is significantly likely to become a public health emergency; and (2) that the circumstances of the existing or potential emergency necessitate a waiver from requirements under the Paperwork Reduction Act. The period of the waiver may not exceed the period of the public health emergency. •Reason not used for opioid public health emergency: Not applicable, because the authority was used. •Last use during a public health emergency: This authority was last used during the public health emergency declared for the opioid crisis in October 2017.
Waiver of public notice process for Medicaid demonstrations under section 1115 of the Social Security Act	•Authority: 42 C.F.R. § 431.416(g) (2017) •Description: This provision allows the Centers for Medicare & Medicaid Services to waive federal and state public notice procedures to expedite a decision on a proposed Medicaid demonstration or demonstration extension request under section 1115(a) of the Social Security Act that addresses a public health emergency. This provision also allows the Secretary of HHS to exempt a state from the normal public notice process or required time constraints when the state demonstrates the existence of unforeseen circumstances resulting from a public health emergency that warrant such an exemption. •Reason not used for opioid public health emergency: Not applicable, because the authority was used. •Last use during a public health emergency: This authority was last used during the public health emergency declared for the opioid crisis in October 2017.
Application extensions and waiver of requirements for block grant funding	•Authority: 21st Century Cures Act, Pub. L. No. 114-255, § 8003 (2016) (codified at 42 U.S.C. § 300x-67) •Description: This provision allows the Secretary of HHS to grant an application extension for or waive compliance with requirements for block grant funding or an allotment authorized under the Protection and Advocacy for Mentally Ill Individuals Act of 1986 during a public health emergency declaration under section 319 of the Public Health Service Act. This authority applies to grants for assistance in the transition from homelessness, grants for community mental health services, and grants for the prevention and treatment of substance abuse and may be exercised, on a state-by-state basis, as the circumstances of the emergency reasonably require. •Reason not used for opioid public health emergency: HHS officials determined not relevant to the opioid crisis; more appropriate to a short, time-limited public health issue or when infrastructure is damaged. •Last use during a public health emergency: According to HHS officials this authority has never been used.

Authority	Description
Funding-related authorities	
Extensions or waiver of sanctions related to submission of data or reports required under laws administered by the Secretary of HHS	•Authority: Public Health Security and Bioterrorism Preparedness and Response Act of 2002, Pub. L. No. 107-188, § 141 (codified at 42 U.S.C. § 247d(d)) •Description: This provision allows the Secretary of HHS to grant extensions or waive sanctions related to submission of data or reports required under laws administered by the Secretary of HHS. To exercise this authority, the Secretary must determine that individuals or public or private entities are unable to comply with deadlines for such data or reports due to a public health emergency declared under section 319 of the Public Health Service Act. The Secretary is also required to notify Congress and publish a Federal Register notice before or promptly after granting an extension or waiver. •Reason not used for opioid public health emergency: HHS officials determined not relevant to the opioid crisis; more appropriate to a short, time-limited public health issue or when infrastructure is damaged. •Last use during a public health emergency: According to HHS officials this authority has never been used.

Enclosure II: Federal Public Health Emergencies, June 2016 through July 2018

The Secretary of Health and Human Services may, under section 319 of the Public Health Service Act, declare a public health emergency if the Secretary determines, in consultation with other public health officials as may be necessary, that: (1) a disease or disorder presents a public health emergency; or (2) a public health emergency, including significant outbreaks of infectious disease or bioterrorist attacks, otherwise exists. A public health emergency declaration is in effect until the Secretary declares the emergency no longer exists or 90 days after the declaration, whichever occurs first. The Secretary may renew the public health emergency declaration for subsequent 90-day periods for as long as the Secretary determines the public health emergency continues to exist. Federal public health emergencies declared since June 2016 are shown in table 3.

Table 3. Federal public health emergencies declared since June 2016

Event	Emergencies declared

ABSTRACT

Antibiotic resistance and its devastating consequences present us with a growing global healthcare crisis. The extensive use and misuse of antibiotics, in particular, and their dissemination in the environment promote the emergence and dissemination of antibiotic-resistant bacteria, thereby posing risks with respect to public health. An urgent need is growing to improve our understanding of the mechanisms associated with the spread and development of antibiotic resistance genes in clinical and veterinary settings, and natural environments.

Keywords: antibiotic resistance, environmental dissemination, antibiotic resistance gene, horizontal gene transfer

INTRODUCTION

For more than seven decades antibiotics have been the cornerstones of modern medicine and have changed the healthcare dramatically by significantly reducing the mortality and morbidity due to infections. Consequently, widespread emergence and dissemination of antibiotic resistance is one of the biggest public health threats in the 21st century. It is estimated that deaths because of drug-resistant microbial pathogens could rise from approximately 700,000 per year to 10 million a year by 2050 [1]. The problem is aggravated further due to rather slow or nil developments of new antibiotics during the past 30 years. Uncontrolled use of antibiotics has led to the development and dissemination of antibiotic-resistant genes in the environment, which is an emerging crisis worldwide. Traditionally, healthcare facilities were thought to be the source of dissemination of antibiotic-resistant genes (ARGs), but recently non-clinical environments were also found to play an important part. Over the last decade, increased resistance against antibiotics among bacteria in many different ecological niches such as soil, wastewater treatment plants (WWTPs), river water, drinking water, seawater, sediments, etc. has been recognized. This is a serious threat that limits our ability to treat common infectious diseases [2-10]. In these different environments, antibiotics (AB), antibiotic-resistant bacteria (ARB), and ARGs have consistently been observed. The reasons for this are multifarious, but the uncontrolled increased use and misuse of antibiotics combined with exposure to additional resistance promoting substances, such as disinfectants, biocides, and some heavy metals, are more significant [2, 11, 12].

ENVIRONMENTAL FACTORS AND ANTHROPOGENIC CONTAMINATION WITH ANTIBIOTICS AND ARGs

Antibiotic resistance is a natural phenomenon that occurs either through a mutation that provides the bacteria with new genes allowing them to survive the effects of the antibiotic (natural selection) or acquisition of resistant genes through gene transfer methods as a part of the evolutionary process. Antibiotics prescribed for certain health conditions after being metabolized by the human body are excreted and when these come into contact with the bacteria (present both inside the gut and the outside environment) induces an antibiotic resistance development process. Hence, the greater the use of antibiotics, the larger the magnitude of antibiotic resistance observed due to selection pressure and survival advantage. Antibiotics of anthropogenic origin and their metabolites can enter the environment through a number of different routes (Figure 1). These routes include soil, water, WWTPs, livestock, and gut microbiota, where each scenario is dealt with in the following sections.

These result in environments where antibiotics, ARGs, resistant bacteria, and environmental bacterial flora are mixed. These types of environments are likely resistant hotspots where ARGs proliferate and new resistant strains develop and disseminate by the horizontal gene transfer method.

Figure 1. Antibiotics and antibiotic resistance genes (ARGs) can disseminate in humans via the environment by various routes.

Soil, Sediment and Solid Waste

Even though the full extent of ARGs in soil is not known, the existing evidence indicates that the soil acts as a vast reservoir as well as a non-point source of ARG-containing bacteria [13]. Since soil receives a large amount of organic material through the application of manure and sewage sludge as fertilizers as well as by dumping of domestic, hospital, and pharmaceutical waste, it becomes a hotbed of antibiotics from various sources to which indigenous microbes, as well as pathogenic bacteria from human and animal refuse, are exposed. A majority of non-pathogenic soil bacteria are found to be multi-drug resistant, reflecting their evolution in an environment containing a wide variety of bioactive molecules. The antibiotic-resistant genes and proteins in environmental bacteria are also found to be homologous to those in pathogenic bacteria. From this observation, it can be suggested that there could be a possibility of horizontal gene transfer from commensals to pathogens. This is also supported by the fact that opportunistic pathogens such as *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, etc. are not only highly drug-resistant but have also displayed a remarkable capacity to acquire new ARGs [14]. In addition, it has been demonstrated that some genetic elements can persist in the environment even after the death of the bacteria [15].

Apart from the soil, another environmental milieu that can serve as the ground for development and transfer of ARGs include water reservoirs, sewage treatment plants, solid waste dumping grounds and agricultural practices particularly livestock rearing. Thus the environment acts as a huge reservoir of ARG-containing bacteria. This whole complement of ARGs present in the environment has been termed ‘environmental resistome.’

Water

Water is not only a non-point source for resistant bacteria, but it also acts as a vector for their transport to different places, for example, rivers and streams transport these bacteria, either in the water itself or from the soil, to distant places. Water sources, particularly those that are close to human activities, have high levels of nutrients and other organic matter that promote microbial growth. These aquatic microenvironments, particularly sewage-contaminated water, harbor proliferating bacteria and also promote the development of antibiotic resistance. Antibiotic-resistant bacteria that develop in these microenvironments can be disseminated to humans and animals through contaminated drinking water [16].

Sewage/WWTPs

Antimicrobial resistance genes (ARGs) in ARB have been identified as widespread contaminants of wastewaters and treated drinking water. Most of the antibiotics prescribed to humans are used in households and eventually end up in the sewage. Therefore, urban WWTPs are one of the main sources of both ARB and ARGs that are released into the environment [6, 17-24]. Apart from the sewage, WWTPs receive wastewater from hospitals (after pre-treatment) where antibiotics are applied on a large scale and the prevalence of ARB and ARG might, therefore, increase in such environments [25, 26]. Hence, from the WWTPs, the antibiotics can end up in sludge dispersed on fields as fertilizer, or released as runoff directly into rivers [27, 28]. Sometimes, wastewater is treated by releasing it into the water or lands, thereby releasing antibiotics into the environment, which may ultimately enter the food chain directly or indirectly [29]. Thus, it is clear that antimicrobial resistance (AMR) hotspots are found not only in medical settings but also in environmental compartments that are subject to some anthropogenic activities. These environmental compartments are considered as hotspots for ARB and ARG spread not only because of the potential presence of substances with selective pressure in the WWTP system [8, 30-32] but also because of the presence of nutrient-rich growth conditions to microorganisms during WWT process that may favor events of horizontal gene transfer. This is evidenced by a number of studies that detected AB, ARB, and ARG in samples from WWTPs around the world [6, 20, 24, 33-36]. Since much of the sewage sludge produced by WWTPs is recycled as fertilizer products and used as a soil conditioner on cultivated areas, and on green areas including parks, private gardens, etc. concerns about the increased spread of AMR through this route has been raised [6, 33, 36]. Drinking water often originates from surface water, which is also the discharge point for wastewater [8, 23, 25]. This is supported by the increasing number of studies demonstrating the presence of antibiotics and ARB in the surrounding water sources and the finished drinking water [25, 37-42]. Another contributing factor is that municipal WWTPs are primarily designed and dimensioned to remove organic matter, phosphorus, and possibly nitrogen, but not antibiotics or other pharmaceuticals [3, 5, 7, 43]. In addition, there are studies that demonstrate that the purification process is not appropriate to completely remove resistance genes in the different compartments of WWTPs, meaning that resistant genes also end up in the environment [43].

Livestock

The antibiotics and antibiotic-resistant pathogens are released into the environment through farm animals, abandoned animals (e.g., cattle in India) and stray animals (e.g., dogs, pigs, and birds). This is because many food-producing animals (e.g., poultry, swine, and cattle) are normally treated with antibiotics in order to prevent infections, to promote growth, and to compensate for unsanitary conditions prevailing in commercial farm units. Thus the regular use of antimicrobials in healthy animals during livestock rearing has resulted in the emergence and increase of antimicrobial-resistant bacteria and makes it difficult to treat infectious diseases. India stands fourth highest in antibiotic consumption (3%) in the livestock sector in the world after China (23%), the United States (13%), and Brazil (9%). In the United States, 80% of sold antibiotics are consumed in the livestock sector alone [44-46]. Recently, an increase in antibiotic-resistant bacterial infections has led to public health concerns about the use of antibiotics for non-therapeutic purposes in animals intended for food production [47]. Resistant microorganisms carried by food-producing animals can spread to humans through consumption of contaminated food and drink, from direct contact with animals, or by environmental exposure, for example, contaminated water. The animal pathogens serve as a donor of antimicrobial-resistant genes to pathogens that infect humans. For instance, the use of a glycopeptide, avoparcin, as a growth promoter in animals in Europe resulted in the expansion of vancomycin-resistant enterococci (VRE) in commensal microorganisms in food animals, on meat from these animals, and in the commensal flora of healthy humans. The subsequent ban on the use of avoparcin in food animals in the European Union reduced the incidence of VRE in animals and its occurrence in the general population. The use of fluoroquinolones (e.g., enrofloxacin) in food-producing animals has contributed to the spread of ciprofloxacin-resistant *Salmonella*, *Campylobacter*, and *Escherichia coli*, which have made human infections difficult to treat. Also, AMR affecting the food supply of one country automatically becomes a potential problem in another country through travel and the import and export of food animals and animal products. In view of the developing resistance, many countries, including the European Union have imposed a ban on the use of some antibiotics in feed or as growth promoters [48].

Gut Microbiota

Humans come into contact with resistant microorganisms through numerous routes, including drinking contaminated water, consuming contaminated vegetables, crops, fish, and meat. The human and animal intestines contain non-pathogenic bacterial species, living as commensals or symbionts. Similar to environmental bacteria, these gut microbes also evolve several resistance genes, which may get selected if they offer a survival advantage during intake of antibiotics or the ARB once entered into the human body can spread ARGs to microflora inhabiting the host through the mechanism discussed earlier [27]. Thus, gut microbiome of both humans and animals serve as a reservoir of ARGs. In addition, antibiotics cause dysbiosis of gut microbiota by obliterating the bacteria that offer colonization resistance. Both these mechanisms together create the paradox of increased susceptibility to infection after the use of antibiotics. Analogous to environmental resistome (defined earlier),

the complement of ARGs in gut microbiome has been referred to as ‘gut resistome’ and they act as reservoirs. Since these genes are already present in the organisms, transfer to pathogenic organisms is more likely than from environmental resistome. For example, a study on *Bacteroides* species has found that tetracycline resistance gene *tet*, present on a conjugative transposon, was found in 20%–30% of isolates before the 1970s in contrast to over 80% in 1990s. The DNA sequence analysis of these genes revealed a high degree of similarity between these genes, indicating frequent occurrences of horizontal gene transfers [49].

Future advances in genome sequencing technologies are likely to facilitate high throughput characterization of the resistome by metagenomic sequencing of the microbiome of patients. This may guide the choice of antibiotics for curtailing infections, at least partially, by the composition and relative abundance of the ARGs in gene reservoir in patients. To fully assess the risks that are associated with the selection of ARGs in GI or genitourinary commensals, we foresee that further studies would be helpful to profile ARGs with respect to their possibility for horizontal gene transfer. However, at present individual monitoring in a clinical setting is not feasible due to the high cost involved.

ANTIBIOTICS USE: PRESENT AND FUTURE TRENDS

It is evident that the major factor driving the increased rate of antibiotic resistance is increased by the use of antibiotics. It was estimated that global antibiotic consumption increased by 36% between 2000 and 2010 and more than half of these were cephalosporins and broad-spectrum penicillins. This study also found that India, China, and the United States were the three largest consumers of antibiotics in 2010, respectively [50]. Though these figures represent the population of these countries to some degree, it is evident that the rampant and unregulated use of antibiotics is a matter of global concern. Particularly in middle-income countries, low public health and sanitation measures are an additional driving force for the increase in antibiotics sales. High population and economic burden promote practices such as over-the-counter sales and financial incentives to prescribe more antibiotics. Similarly, there is a greater burden of food production which leads to excessive use of prophylactic antibiotics in animal rearing practice. A recent study has pointed out that antibiotic use in the livestock sector in India is expected to notice the biggest increase, that is, 82% by 2030. It is projected that India will notice the highest growth rate in antibiotics use in animal farms between now and 2030 for the mass production of food animals [51]. Since indiscriminate use of antibiotics is the main reason for the rapid rise of antibiotic resistance, this problem needs to be addressed to slow down the emergence of newer ARGs.

MITIGATING STRATEGIES FOR ANTIBIOTIC RESISTANCE

One Health Concept

Since antibiotic resistance genes are persistent in environmental and human-animal health interfaces, an approach which deals with all the three areas is required, which highlights the

One Health approach [16]. The One Health approach, is defined as ‘the mutual effort of various disciplines – working locally, nationally, and worldwide – to accomplish optimal health for humans, livestock and our environment’ [52]. This approach perceives that human health is linked to the health of animals and the environment and is applicable to the problem of antibiotic resistance as well. Role of livestock in the dissemination of ARGs is due to use of many antibiotics in animal rearing, in sub-therapeutic doses and with elongated exposure periods, these production systems generate perfect milieu for bacteria for horizontal gene transfer that confers resistance. These genes can consequently be transmitted to human-adapted pathogens or to the human gut. The fact that the antibiotics used in human and animal health largely comprise the same molecules would be expected to commute the transmission of resistance between animals and humans, either directly or via the environment.

The One Health approach for dealing with AMR, encircling all three pillars (human health, animal health, and environmental health), will depend on sound knowledge about the ways how all three pillars interrelate in transmission to human and mechanisms involved (Figure 2).

Figure 2. Role of three pillars (human health, animal health, and environmental health) of one health concept in the dissemination of antibiotic residues, antibiotic-resistant bacteria, and antibiotic-resistant genes in the environment.

Surveillance

Antibiotic resistance has its foundation on accelerated misuse and overuse of antibiotics along with poor infection prevention and control. Surveillance to estimate the exact magnitude of this problem, public awareness, and regulation of antibiotic use are the key elements for reducing the escalating rates of antibiotic resistance. In October 2015, WHO launched the Global Antimicrobial Surveillance System (GLASS), allied with WHO Collaborating Centres and existing AMR surveillance networks. So far, 52 countries are enrolled in GLASS out of which 40 countries provided information about their national surveillance systems and 22 countries also provided data on levels of antibiotic resistance for their first report. It has revealed the spread of antibiotic resistance across these 22 countries. The United Nations Interagency Coordination Group on Antimicrobial Resistance has been formed in 2016 with the mandate of providing practical guidance for sustained effective global action to address AMR. In developing nations like India, AMR is of particular concern due to the high burden of infectious diseases and low availability of resources. In 2011, the Health Ministers of the WHO South-East Asia Region pledged to combat drug resistance through the Jaipur Declaration. Since then, there has been a growing awareness of the need for appropriate tracking of drug resistance, and all countries have agreed to contribute information to a regional database. The Indian Council of Medical Research (ICMR) in 2013 set up an AMR surveillance network which is currently networking the tertiary care hospitals in the country. This network has been established with the aims of (i) collecting a nationally representative data on drug resistance and monitor trends across the country, (ii) generating evidence on mechanisms of resistance in different pathogenic groups, (iii) guiding antimicrobial policies for both treatment and prophylaxis, and (iv) directing hospital infection control efforts that facilitate prevention of the spread of resistant organisms.

Filling the vast gap of new antibiotic development is another step that will address this issue. An initiative in this direction is the establishment of the Global Antibiotic Research and Development Partnership, a not-for-profit research and development (R&D) organization. This organization is focused on developing and delivering new or improved antibiotic treatments and endeavoring to ensure their sustainable access at a global level.

Box 1.

- Strengthening of surveillance data
- Increasing public awareness regarding antibiotic resistance
- Strengthening government commitment to improve the practices of antibiotic prescription
- Optimizing the use of antimicrobials and restricting the over-the-counter sale of antibiotics
- Undertaking strategies for improving sanitation, malnutrition, and endemic infections
- Implementing preventive measures against infections, for example, vaccination for reducing clinical trial risk
- Strengthening the regulatory policies of farm feeding of antibiotics
- Formulating and implementing measures to properly dispose of biological waste
- Establishing guidelines for soil and water safety to reduce the pool of antibiotics and ARGs in the ecosystems
- Assuring the quality of generic antibiotics
- Sharing of data as early as possible
- Organizing World Antibiotic Awareness Week
- Establishing global partnerships for coordinated measures

Strong political will is required to formulate and implement regulations regarding antibiotic use. In addition, a collaboration between governments, research organizations, pharmaceutical companies, and healthcare providers is required for rapid communication of information. In summary, the steps required to combat this problem are provided as follows (BOX 1) [53-55].

CONCLUSION AND OUTLOOK

Antibiotic resistance is a natural phenomenon which is promoted by human activities. Lack of awareness and rampant unscientific use of antibiotics for short-term economic gains has escalated antibiotic resistance disproportionately. The assessment of the overall burden of resistance is difficult but mortality is clearly greater in vulnerable groups such as neonates. The environment plays a key role as a reservoir and source of dissemination of ARGs and several environmental regulatory measures are required to adequately address this issue. Preventive measures to reduce infections in the community, as well as reared animals, will go a long way to reduce the ARG pool, as will soil and water safety measures. Political commitment, global partnerships, and public awareness are most essential to tackle this problem systemically. In addition, newer alternative methods of treatment of infections will reduce the use of antibiotics, thus reducing infections as well as the emergence of resistance.

Chapter 531

**CARTELS AND THE U.S. HEROIN EPIDEMIC:
COMBATING DRUG VIOLENCE AND
PUBLIC HEALTH CRISIS***

Committee on Foreign Relations

THURSDAY, MAY 26, 2016

U.S. SENATE,

SUBCOMMITTEE ON WESTERN HEMISPHERE, TRANSNATIONAL CRIME,
CIVILIAN SECURITY, DEMOCRACY, HUMAN RIGHTS, AND GLOBAL WOMEN'S
ISSUES,

Committee on Foreign Relations

The subcommittee met, pursuant to notice, at 9:03 a.m. in Room SD-419, Dirksen Senate
Office Building, Hon. Marco Rubio, chairman of the subcommittee, presiding.

Present: Senators Rubio, Gardner, Boxer, Kaine, Menendez, and Markey.

**OPENING STATEMENT OF HON. MARCO RUBIO,
U.S. SENATOR FROM FLORIDA**

Senator RUBIO. Good morning. This hearing on the Subcommittee of the Western Hemisphere, Transnational Crime, Civilian Security, Democracy, Human Rights, and Global Women's Issues will come to order. I thank you for being here today.

The title of this hearing is "Cartels and the U.S. Heroin Epidemic: Combating Drug Violence and Public Health Crisis."

* This is an edited, reformatted and augmented version of Hearing before the Subcommittee on Western Hemisphere, Transnational Crime, Democracy, Civilian Security, Human Rights, and Global Women's Issues, Committee on Foreign Relations, United States Senate, One Hundred Fourteenth Congress, Second Session, dated May 26, 2016.

Before we begin the meeting, on a matter of personal privilege, I wanted to acknowledge the contributions of a loyal and a dedicated staffer because behind every one of us here in the Senate, there are loyal and really hardworking people. Literally they sit behind us at these meetings, and they do all the hard work behind the scenes to make sure that we are briefed and prepared to cast votes and advance public policy that makes a difference.

Since 2011, Maggie Dougherty has been an instrumental part of our policy team, and she has logged in countless hours working on all sorts of complex and important issues for our office. She has also logged in countless hours sitting behind us here in these committee meetings, but no longer. Today is Maggie's last Senate Foreign Relations Committee meeting. In a week's time, she will depart our office to even a bigger and better opportunity. So I just briefly wanted to thank her for everything she has done for us. We are very proud of her work. [Applause.]

Senator RUBIO. So the title of this hearing, "Cartels and the U.S. Heroin Epidemic"—we have two panels testifying. The first is an official panel that will feature Mr. Daniel Foote, the Deputy Assistant Secretary of State for the Bureau of International Narcotics and Law Enforcement at the U.S. Department of State, and Mr. Kemp Chester, the Associate Director for the National Heroin Coordination Group for the Office of National Drug Control Policy.

The second panel will present the Honorable Teresa Jacobs, the Mayor of Orange County, Florida, and Mr. Steven Dudley, the Co-Director of InSight Crime.

Thank you all for being here today. We appreciate your time. We appreciate your dedication. I would also like to thank all of those who worked alongside my staff and making this hearing possible.

Drug cartels operate out of countries in the western hemisphere, and they do so by using sophisticated distribution systems that move narcotics into and across the United States. Heroin supplied by these cartels has created a public health epidemic and fueled drug violence across this country.

The heroin epidemic, drug war, and fight against drug violence are, unfortunately, becoming part of everyday events in our society. It is our duty to find the best possible avenues and allocate resources to provide the best tools to equip those on the front lines to fight this public health crisis. We need to examine what the United States, Mexico, and other regional partners are doing to cooperatively address the rise in heroin and in drug trafficking. Promoting the efficacy and proper execution of U.S. initiatives to stop the spread of heroin and combat the drug cartels should be one of our top priorities.

Here are some facts. One of the primary culprits in this fight is called fentanyl. It is a synthetic opiate that is 25 to 40 times more potent than heroin and it may be used to treat pain associated with advanced cancer. While fentanyl is legally prescribed in the United States, the CDC states that most cases of fentanyl-related overdoses are associated with non-pharmaceutical fentanyl. It is a type used as a substitute for heroin or mixed with heroin or other drugs, sometimes without the user's knowledge.

In 2015, the DEA's National Drug Threat Assessment Summary reported that Mexico and China have been cited as the primary source country, though some analogs of fentanyl are manufactured in China. These supplies are often trafficked into the United States across the southwest border or delivered through mail couriers. Transnational criminal organizations also use Florida as the point of arrival for South American cocaine and heroin. Much of the illegally diverted and produced fentanyl is found in the same U.S. markets where white powder heroin is found.

According to the Substance Abuse and Mental Health Services Administration, the estimated number of individuals who used heroin was 914,000 people in 2014.

In addition, there are about 586,000 individuals, or basically .2 percent of the 12 and older population, who had a heroin disorder in 2014.

While there has been an increase in heroin overdoses and heroin-related deaths across the United States, the Midwest and the Northeast regions have been areas of particular concern. To this day despite the administration's efforts, heroin-related overdose deaths increased by 244 percent between 2007 and the year 2013.

The U.S. has responded to such findings by launching the Heroin Response Strategy, leveraging upon the 15 high intensity drug trafficking areas across the country.

Mexico, our regional partner, has displayed willingness to cooperate with U.S. authorities, but despite these operations, the International Narcotics Control Strategy Report estimates that less than 2 percent of cocaine that comes through Mexico is seized by this country's authorities. Under the Merida Initiative, Congress has provided billions in funds to the Mexican Government to improve security and the rule of law, and I applaud the continued efforts of the Mexican Government to continue its drug crop eradication efforts and to arrest drug kingpins. However, we are still far from the finish line.

I think the Congress can continue to work in constructive ways to promote legislation addressing opiate abuse. I am proud to be the cosponsor of the Comprehensive Addiction and Recovery Act, a bipartisan bill that overwhelmingly passed the Senate. I also applaud the House for working to address this issue, and I hope soon we will be able to send this legislation to the President's desk.

It is my hope that today's hearing will shed light on the consequences that this epidemic will have in our society and future generations if left unaddressed and not given proper attention. I am optimistic this hearing will serve as the opportunity to learn about the administration's priorities in combating the heroin epidemic and drug violence. And I hope you will address these issues in your testimony as well.

With that, I will now turn it over to our ranking member, Senator Boxer, for her opening statement.

STATEMENT OF HON. BARBARA BOXER, U.S. SENATOR FROM CALIFORNIA

Senator BOXER. Mr. Chairman, thank you so much for holding this important hearing.

The abuse of illegal and legal drugs in America is an absolute crisis, and to fight it, we need to act on many fronts.

Take the case of opioids. These are legal prescription drugs that are killing approximately 125 people every single day here at home. The CDC says that in 2014, 47,000 people died from opioid abuse. Just imagine that.

We need to do much more than we have done so far to put real dollars behind the effort to stop this madness.

Then there is the issue we will focus on today of illegal drugs being transported into this country.

Recently I visited Costa Rica, and I learned that this peaceful country is very alarmed about drug cartels infiltrating their population. We must help them stop this real threat. And I hope to ask a question about that.

And while we are working cooperatively with the Mexican Government, specifically an initiative called the Merida Initiative, and while we have to date seized more than \$4 billion in narcotics and illicit currency, let us face it. That is a drop in the bucket. We simply have to address the demand in the United States for these lethal products. And I know that is not your job, and I am not going to even ask you about that. But I am making a statement as a United States Senator. We have to address the demand in the United States for these lethal products.

Supply and demand go hand in hand. A long time ago, I was an economics major. It is like economics 101. When people demand a product, we know what happens. The supply will come. And when even more people demand a product, the price will go up and it goes around in a circle.

Years ago, too many to even mention—so I do not even know where my chairman was at that time it was so long ago, very long—when I first came to Congress, I wrote a bill called Treatment on Demand because what I found out, Mr. Chairman and members, is that when there is a person in America with a terrible addiction, at that time—and it is so true today—they wake up one day and they say I have done it, I have had it, I need a new life. They cannot get in anywhere. So people say, very good, come back in 2 weeks. This is an emergency circumstance in many ways, but it is not considered that. So they will go in. Maybe they will get a pat on the back. Come back in 2 weeks. And by then, maybe they have even overdosed.

Now, I know we are working with Colombia and Guatemala helping farmers develop alternatives to opium production. But again, we need to be even more aggressive in our policies regarding drug production, trafficking, and consumption here at home.

In California, we have four of those areas that my chairman spoke about that are designated as high intensity drug trafficking areas by the Obama administration. I am extremely grateful to the administration. We had that help under George Bush as well. When you identify an area, it means you are going to get some attention, some Federal dollars, some Federal help because a lot of these local people, our police forces and so on, really do need that help. So I am very grateful for that.

We have also discovered tunnels from Mexico to San Diego, which act as conduits for thousands of pounds of cocaine. And this points to the continuous challenges we face in dealing with these dangerous cartels. They are really good at what they do, and they intimidate everyone. And that is why this fight is so critical. We need even stronger partnerships with Mexico and other countries in the region.

And I want to say this. Alienating our Latin American neighbors and our Latinos here at home is the worst possible thing we can do, first of all, on a human level because in my view it is prejudice and bigotry. But it does not make sense if we are really trying to crack down on these cartels. We need our friends to work with us. We do not need to escalate some kind of ridiculous debate about walls and all the rest.

I do want to thank our witnesses for being here today. There is a lot of burden on you, and this is very difficult. The war on drugs has not been a success. And I think the reason is we have not done enough on the demand side or on any side. We need to do much better.

And I want to thank my chairman because I think this is really well-timed given what we are facing with the opioid crisis. Thank you.

Senator RUBIO. Thank you, Senator Boxer.

Before we begin with the testimony, I did want to recognize the senior Senator from New Jersey, who has done an extreme amount of work on western hemisphere issues but also issues regarding transnational crime, if he wanted to give any opening comment.

Senator MENENDEZ. No, thank you.

Senator RUBIO. With that, please join me in welcoming our first witness, Mr. Foote. Thank you for your testimony before us here today.

**STATEMENT OF DANIEL L. FOOTE, DEPUTY ASSISTANT SECRETARY
OF STATE, BUREAU OF INTERNATIONAL NARCOTICS AND LAW
ENFORCEMENT U.S. DEPARTMENT OF STATE, WASHINGTON, D.C.**

Mr. FOOTE. Chairman Rubio, Senator Boxer, Senator Menendez, Senator Gardner, thank you for this opportunity to appear before you to discuss the work of the State Department's Bureau of International Narcotics and Law Enforcement Affairs to combat the production and trafficking of heroin particularly by Mexican-based drug trafficking organizations that are responsible for the vast majority of the heroin on America's streets today.

In the United States, we face an epidemic of opioid abuse. Well over half of the more than 47,000 American deaths from last year were due to either domestically produced controlled prescription pain relievers or heroin, which is often combined with other deadly drugs such as fentanyl.

In Mexico, drug trafficking organizations have killed tens of thousands of citizens, and these organizations continue to foment violence, instability, corruption, and addiction.

This scourge is broader than just the United States, and we will not solve it alone.

The overwhelming majority of the heroin in the U.S. is produced or distributed by Mexican drug trafficking organizations. For many years, they have been trafficking not only heroin but also much of the cocaine, methamphetamine, and other illicit drugs that enter our country. Most of these drugs enter through our border with Mexico.

The United States and Mexico developed the Merida Initiative in 2007 with major focus on combating the production and trafficking of illicit drugs across our borders. Today the Pena Nieto and Obama administrations remain committed to Merida's strategic goals. Our Merida partnership, which brings together significant investments and capabilities of both countries, continues to help build Mexico's capacity to fight narcotics trafficking, organized crime, and violence. Together, we are aggressively responding to this threat by putting the leaders of drug trafficking organizations in jail, by seizing their drugs and money, and by dismantling their organizations. Today, through Merida, INL is professionalizing and building the capacity of Mexican law enforcement agencies, supporting the Mexican Government's efforts to strengthen border management and security, and helping advance reform across Mexico's justice sector.

Bilaterally we have agreed that targeting the production and trafficking of heroin, as well as fentanyl and other dangerous synthetic substances, is a top shared priority. To that end, INL and DEA are providing training to law enforcement officers, investigators, and analysts

increasing Mexico's ability to identify, investigate, and dismantle clandestine heroin and fentanyl labs.

With our interagency partners, we are also improving information sharing between our governments on heroin and fentanyl working together to get better assessments on opium poppy cultivation and heroin and fentanyl production in Mexico and continuing to explore other avenues to enhance our bilateral cooperation and effectiveness.

Building strong, effective Mexican justice sector institutions, capable of confronting organized criminal enterprises, is a difficult, long-term challenge. This work must be sustained, for it is only through a committed, coordinated effort that sustainable capacity to deter the cultivation, production, and trafficking of illicit drugs will be strengthened. The significant investments of both of our governments are producing results, and with your continued support, this successful collaboration with Mexico will continue.

Thank you.

[Mr. Foote's prepared statement is located in the Additional Material Submitted for the Record section at the end of this transcript.]

Senator GARDNER [presiding]. Thank you, Mr. Foote.

Mr. Kemp Chester, Associate Director for the National Heroin Coordination Group, please begin your testimony. Thank you.

STATEMENT OF KEMP CHESTER, ASSOCIATE DIRECTOR FOR THE NATIONAL HEROIN COORDINATION GROUP, OFFICE OF NATIONAL DRUG POLICY, WASHINGTON, D.C.

Mr. CHESTER. Chairman Rubio, Ranking Member Boxer, and members of the subcommittee, thank you for inviting me here this morning to discuss the public health and public safety issues resulting from heroin use, the Government of Mexico's efforts to reduce the availability of heroin in the United States, and U.S.-Mexico cooperation to address heroin issues in both countries.

In 2014, the most current year for which we have data, more than 47,000 Americans, or approximately 129 people each day, died from a drug overdose. Of the overdose deaths in 2014, 22 percent involved heroin.

The threat posed by heroin has continued to grow dramatically over the past several years, and since 2007, deaths involving heroin have risen 340 percent from 2,402 in 2007 to 10,574 in 2014.

Heroin use has spread into suburban and rural communities and is growing among most socioeconomic classes, age groups, and races.

Mexico is currently the primary supplier of heroin to the United States with Mexican drug traffickers cultivating opium poppy, producing heroin, and smuggling the finished product into the United States. Poppy cultivation in Mexico has increased substantially in recent years, rising from 17,000 hectares in 2014 to 28,000 hectares in 2015, which could yield potential production of 70 metric tons of pure heroin.

The heroin crisis is being compounded by the reemergence of illicit fentanyl, a powerful synthetic opioid more potent than heroin.

Illicit fentanyl is sometimes mixed with powder heroin to increase its effects or mixed with dilutants and sold as synthetic heroin. Increasingly fentanyl is being pressed into pill form and sold as counterfeit prescription opioid pills. The majority of the illicit fentanyl in the U.S. is clandestinely produced in Mexico or in China.

Fentanyl is extremely dangerous and deadly. In 2014, there were more than 5,544 drug overdose deaths involving synthetic narcotics other than methadone, a category that includes fentanyl. This number has more than doubled from 2 years earlier.

U.S.-Mexico engagement regarding heroin has been robust. In October 2015, ONDCP Director Michael Botticelli participated in a bilateral security dialogue where the importance of increased poppy eradication efforts by the Government of Mexico, as well as drug interdiction, clandestine laboratory destruction, and the disruption of precursor chemical trafficking were all highlighted.

In early March, Director Botticelli, Ambassador William Brownfield, the Assistant Secretary of State for International Narcotics and Law Enforcement Affairs, and I met with the Mexican Attorney General Gomez, and she announced her role as the synchronizer of Mexico's efforts to disrupt the production of heroin and illicit fentanyl. Importantly, we agreed then to jointly develop a focused national plan to concentrate Mexico's efforts against heroin and fentanyl.

The urgent need to sustain progress toward addressing the Nation's heroin and fentanyl crisis requires increased collaboration between Federal agencies and with our partners working at the State, local, and tribal level where the crisis is felt most deeply.

In November 2015, the team that I lead, the National Heroin Coordination Group, was created within the Office of National Drug Control Policy to form the hub of a network of interagency partners who will leverage their home agency authorities and resources and to harmonize interagency activities against the heroin and fentanyl supply chains to the United States.

The ONDCP-funded high intensity drug trafficking areas, or HIDTA program, the locally based program that responds to drug trafficking issues facing specific areas of the country, has also been instrumental. In August 2015, ONDCP committed \$2.5 million in HIDTA funds to develop a heroin response strategy. This innovative project combines prevention, education, intelligence, and enforcement resources to address the heroin threat through seven regional HIDAAs covering 17 States and the District of Columbia.

So while we have laid a firm foundation to address the heroin crisis, much remains to be accomplished. For example, we do have gaps in our capability to detect illicit fentanyl at our borders, and our Mexican partners could certainly do more in the areas of opium poppy eradication and clandestine laboratory identification and neutralization.

And while my remarks have focused on addressing the supply side of the opioid crisis, we must address opioid use disorders with a balanced approach that also regards addiction as a public health matter, using substance abuse prevention and treatment strategies and recovery support services. In his fiscal year 2017 budget, President Obama proposed \$1 billion in new mandatory funding to expand the availability of evidence-based strategies such as medication-assisted treatment and to extend the availability of substance abuse treatment providers.

ONDCP will continue to work with our international partners, Federal Government Departments and agencies, and our partners at the State, local, and tribal levels to reduce

heroin and fentanyl production and trafficking and the profound effect these dangerous drugs are having in our communities.

Thank you for the opportunity to testify today, and I would be happy to answer any of your questions.

[Mr. Chester's prepared statement is located in the Additional Material Submitted for the Record section at the end of this transcript.]

Senator RUBIO [presiding]. Thank you.

And I am going to defer my questions because I know members need to be in other places, and I will basically be here throughout the duration. And so I will turn over to the ranking member for her questions.

Senator BOXER. Thanks. I just have two questions for Mr. Foote. So, Mr. Chester, breathe. You are off the hook here.

Mr. Foote, in 2008, Mexico's Congress passed a series of significant reforms to its criminal procedures, new laws to promote greater access to justice, and strengthened measures to combat organized crime, measures that would make the Mexican justice system look a little bit more like our own. These reforms were intended to be implemented by 2016. Where does the implementation of these judicial reforms stand, and how has the United States assisted in this process? And how do you feel about whether they are really doing what they committed to do?

Mr. FOOTE. Thank you, Senator.

As you know, Mexico committed and passed legislation to implement a new criminal justice system which is an accusatorial justice system, much like ourselves. At this point, of the 32 Mexican states, 24 have implemented this with federal level crimes and I believe 9 have implemented it at state level crimes. Obviously, this is a long-term process, and some of the states in Mexico will not meet next month's deadline.

We remain committed and continue to work closely with them on a number of issues. Thanks to the gracious appropriations of Congress, we have dedicated approximately \$250 million to these efforts between the Department of State and USAID through issues such as training judges, prosecutors, courtroom personnel, law students. Over 4,000 have been trained to date through Department of Justice's OPTAT prosecutorial training program. We also have a number of law school and institutional exchange programs through the American Bar Association and a number of universities here in the United States.

We are preparing law enforcement for their new roles in the accusatorial justice sector. For instance, our Department of Justice partners in ICITAP have trained thousands of law enforcement in crime scene investigations, provided equipment for units and forensics, fingerprinting, and other collection there so that Mexico can comply with international standards.

Senator BOXER. Okay. Thank you. What I am getting from you is that there is progress being made, although not everyone will meet the deadline. It is an optimistic report.

And so that leads me to my final question, which I alluded to in my statement. As we continue to work with the Mexican Government—and that is just critical. We have to. We have to work here at home to reduce the demand. We have to work across the border to reduce the supply. And that is where the rubber meets the road in both of these areas where we need to work with Mexico.

I am concerned about the rhetoric in the presidential campaign describing our relationship with Mexico. I know it is a tough question for you. I just want you to say what you feel in

your heart because we need to know. Mexican officials have said on the record that some of the proposals mentioned on the campaign trail—we know who we are talking about here, a candidate who is talking about building a wall, having Mexico do it, insulting Mexican Americans here at home—that some of the proposals would have a cataclysmic effect on our bilateral relations.

Has this divisive rhetoric affected diplomatic relations with Mexico at this point? Has it impacted the United States' ability to work with the Mexican Government to combat drug trafficking? And are you concerned that that type of rhetoric could just completely undermine what we are trying to do here?

Senator RUBIO. Just for the record, she is not talking about me. [Laughter.]

Senator BOXER. I am so not talking about you.

Mr. FOOTE. Excellent. Well, I will try to strike a balance between answering your question and not entering too deeply into our own domestic politics here.

Senator BOXER. I know it is a tough one, but you know what? When people talk, it has real-life impacts, especially presumptive nominee.

Mr. FOOTE. You have all seen some of the reactions from south of the border from our Mexican brothers and sisters. You have seen President Vicente Fox's reactions and others.

From the embassy bilateral level to date, we continue to work very closely together. In my personal opinion, I do not believe it has gravely affected our ability to do business together. Mexico in the last several months has reiterated its commitment to continuing with the Merida Initiative. Where the populace of Mexico stands on this may be another matter. But we continue to be able to work closely together bilaterally on all——

Senator BOXER. So the words have not had an impact on what is going on at the very top levels in your opinion on the work that you were doing at this point.

Mr. FOOTE. Not in their dealings with us.

Senator BOXER. That is excellent.

Now we have to make sure that those policies never come into effect.

Thank you very much.

Senator RUBIO. Thank you, Senator Boxer.

Senator Menendez?

Senator MENENDEZ. Thank you, Mr. Chairman, for calling the hearing. It is an important one.

And thank you both for your service to our country.

Mr. Foote, how many agencies are involved in interdiction and eradication efforts with respect to Mexico's border with us in our efforts to stop interdiction, stop flows, use intelligence? How many agencies are involved?

Mr. FOOTE. U.S. agencies I hope is what you are asking?

Senator MENENDEZ. U.S. agencies.

Mr. FOOTE. Thank you. INL, Department of State. You have Department of Justice, DEA, FBI to a certain extent. Department of Homeland Security is heavily involved through Customs and Border Protection, Immigration and Customs Enforcement, Homeland Security investigations. Our military supports some of the border efforts of Mexico's military. And then we have some ancillary agencies who are based in Mexico City, but while their chief focus is not the border, they do peripherally work on it such as ATF and the U.S. Marshals.

Senator MENENDEZ. And if you had to guess how much money has been spent on interdiction and eradication efforts in Mexico since the start of the epidemic that we are experiencing here, would you put it at?

Mr. FOOTE. My understanding is \$2.5 billion has been appropriated, of which approximately \$1.5 billion has been obligated or committed to specific projects, of which we still have at this point new initiatives for about \$700 million.

Senator MENENDEZ. Now, are you speaking just Merida specifically?

Mr. FOOTE. Pardon me?

Senator MENENDEZ. Are you speaking just of Merida specifically? Mr. FOOTE. Largely.

Senator MENENDEZ. There is money spent far beyond Merida.

Mr. FOOTE. There certainly is, Senator. I am not in a position to comment on Department of Justice's appropriation. I just do not have the figures. That is something we could get for you.

Senator MENENDEZ. I was not looking just at appropriation. I look at all the agencies you mentioned, your own, INL, Department of Justice, DEA, FBI, Homeland Security, Immigration, military, Alcohol, Tobacco and Firearms. And I think to myself it has to be billions collectively. And I was one of the architects of the Merida Initiative, which I support.

But \$1.5 billion later, billions between all of our respective agencies, and what we have is an opioid epidemic. And as a policy-maker, one has to take a step back and say to themselves, what is not working because something is not working. If billions of dollars later what you see is a spike versus a trend in the other direction, then something is not working. So if I were to say to you, what is not working, what do we need to change, your answer would be?

Mr. FOOTE. First of all, Senator, I think we have in the past few years come to the realization that this is a shared responsibility between the United States and source countries and trafficking countries. I am heartened by the Senate's recent passing of the opioid legislation. It is something that is going to help us. Certainly Mexico-specific, their capacities are far greater than they were when we started the Merida Initiative in 2007. Information sharing and collaboration has led our own U.S. law enforcement agencies to interdict significantly more on our southern border due to Mexico cooperation.

We still do have a way to go. I think we also need to get better here in the United States at demand reduction and treating the health issues of addicted people. It is a shared responsibility and it is no longer just a supply-side issue.

Senator MENENDEZ. So as I listened to your response, it is everything that we are doing except for a more significant effort on demand reduction, but it is not suggesting that there is anything that we are not doing. And all I can look at and say if you are spending billions and instead of the trend going the opposite direction, it is rising, you have to raise the question what is it that we are either doing wrong or what is it that we are not doing that we need to do in order to meet the challenge because otherwise we can appropriate billions and billions, but still find ourselves in a trend that is undesirable.

So the only thing I heard from you in your response to me was doing more demand reduction, which I certainly believe is true. But I did not hear about anything else. So you know, you have to question whether or not the continuation of this type of expenditure in this manner is the right policy.

Let me ask you this. Do you believe that there is sufficient coordination, a seamless coordination between at least on our side of the border as it relates to all the agencies that you suggested are engaged in this fight?

Mr. FOOTE. Senator, obviously, we can always get better at everything we do. Department of State kind of works from the southern border south. So I do not feel that it is our position to comment on interagency coordination north of the border. South of the border, we have robust interagency coordination through the country team at Embassy Mexico City. We can always get a little better there.

Senator MENENDEZ. Your Mexican partners—are they doing everything that they can in order to meet the challenge on their side of the border?

Mr. FOOTE. During the beginning part of President Pena Nieto's administration, there was a pause in Plan Merida as I think we did a mutual assessment of the security relationship, particularly on their side, and over the past year and a half, we have seen much closer collaboration, an unprecedented openness and frankness in our bilateral dialogue.

To answer your question, is Mexico doing everything that they can, they could improve. Some of their efforts are not yet at the optimal level, but we remain optimistic and positive that they are moving in the right direction.

Senator MENENDEZ. Well, I appreciate the optimism, but I am seeking to introduce a little dose of realism into it. And so part of the challenge is that you have lawless states in some of the northern part of Mexico where I have heard U.S. citizens from the region who have come to talk to me say that many who had businesses, longtime relationships on the immediate other side of the border, that basically cannot operate there because the federal government's presence—i.e., the federal government of Mexico's presence—is not there. So if you have lawlessness and if you have uncontrolled states, then you have the opportunity for drug traffickers to avail themselves of that. And it seems to me that while I am an incredibly strong and have been for 25 years supporter of the U.S.-Mexico relationship, we need to be honest in this relationship in order to make sure that we are making the progress that we need here and for Mexico to be able to regain its sovereignty over parts of northern Mexico that it presently does not have.

Thank you, Mr. Chairman.

Senator RUBIO. Thank you.

Let me use some of my time that I yielded just to interject, to follow up on that.

Secretary Foote, how would you assess the assertion made by a group of experts from the Inter-American Commission on Human Rights that there may have been another bus involved in the incident in which 43 students disappeared in Guerrero, Mexico that was packed with heroin bound for the U.S.?

Mr. FOOTE. Senator, thank you for that question. Given that we have not seen the results of the final investigation from Mexico, I am not in a great position to answer that question right now. We would be happy to answer that for the record in writing.

[The material referred to above was not available when this transcript went to press.]

Senator RUBIO. Okay.

Senator KAINE?

Senator KAINE. Thank you, Mr. Chair, and thanks to the witnesses.

First, to get an idea of the scope of this challenge on the Mexican side in terms of the black tar heroin, is the poppy production for this heroin still significantly confined to the state

of Nayarit or is it more broadly distributed? Mexico is a big country. So when we talk about a problem in Mexico, I worry that we are not being specific enough.

Mr. CHESTER. Yes, Senator. Our latest crop estimate that was produced about 2 months ago shows two major growing areas in Mexico, one in the state of Guerrero and then another in what is called the tri-border region up in the northern part of the country. Those are the two major growing areas in Mexico, with very, very small kind of sporadic spots in other parts of the country, but they are basically concentrated in those two areas.

Senator Kaine. And then the fentanyl is made in labs, and I gather that most of the fentanyl that comes in is either coming in— it is made in China and may be transited in through Mexico or also made in labs in Mexico. Are those the two main sources for fentanyl?

Mr. CHESTER. That is correct.

And I will tell you that our understanding and our awareness of fentanyl traffic has evolved dramatically over the last 6 months as we have seen the crisis rise. So in order of magnitude, I cannot tell you, but what I can tell you is that China is a significant supplier of fentanyl to the United States or it is ordered by individuals on the dark web around the Internet and then, using parcel post or the Postal Service, shipped directly to them.

We also know that fentanyl is shipped into Mexico in some cases mixed with dilutants and smuggled across the Southwest border and that there are precursor chemicals that are shipped into Mexico that can be used for the production of clandestine fentanyl in laboratories in Mexico. So as you look at the vectors coming into the United States, those are the two main ones that we see for finished fentanyl coming into the United States or its manufacture in Mexico.

Senator Kaine. I want to talk, Mr. Chester, about your written testimony. I am sorry I did not get here for your entire oral testimony.

But on page 1, there are several principal factors contributing to the current nationwide heroin crisis: the increased availability of heroin in the U.S. market, the availability of pure forms of heroin that allow for non-intravenous use, its relatively low price, and a relatively small percentage of non-medical users of opioid prescription drugs transitioning to heroin.

I am trying to unpack that statement, and I am wondering if your statement puts enough of a finger on the prescription opioid problem. I have heard it stated through Michael Botticelli and others that 80 percent of those who OD on heroin in this country, not fatal ODs but total ODs, started their addiction to opioids by being addicted to prescription opioids and then transition to heroin because they could get it for a lower price. Is that an accurate statement?

Mr. CHESTER. No, Senator. And I am glad you asked that question. Of the numbers of individuals who non-medically use opioids and then transition into heroin, that number is actually relatively small. It is about 3.6 percent.

Senator Kaine. For non-medical use.

Mr. CHESTER. That is correct. So the non-medical use of a prescription opioid like OxyContin and kind of the traditional “got it from the medicine cabinet, got it from friends or family members”—the percentage of those individuals who transition to heroin use is relatively low. It is about 3.6 percent.

But conversely, of individuals who are non-treatment users of heroin, 80 percent of them actually abused a prescription opioid in the past. So while there is not a direct causation between the two, the non-medical use of opioids is a strong risk factor for eventual heroin use.

Senator Kaine. And even the medical use of opioids can be a risk factor for eventual heroin use. Correct?

Mr. Chester. Yes, Senator, that is right. So an opioid in and of itself and its effect on the body—obviously, it is a very addictive drug and affects the body in unique ways, as an opioid. So those individuals who take opioids, whether they get them from a doctor or whether they get them from a friend or a family member for non-medical reasons are at risk for eventual opioid addiction if not used properly. That is correct.

Senator Kaine. And you cite in the testimony the relatively low price of heroin—and that is relatively low compared to past trends but also compared to the cost of opioid-based prescription drugs. Correct?

Mr. Chester. That is correct. So the street price of a gram of heroin compared to the street price, if you will, of an opioid pill or an oxy pill or something of that nature, that is correct. That is what we consider to be one of the contributing factors. So it is the availability and the general low price and then the purity that have all been contributing factors to the current crisis that we are in with heroin. That is correct.

Senator Kaine. Mr. Foote talked about the work that we have done in this body and we are trying to harmonize with the House in this recent CARA, Comprehensive Addiction and Recovery Act. We really believe it here—and I think it is now bipartisan—we are seeing in all of our States that if we do not get a hold of the culture of over-prescription of opioid-based prescription drugs, we are just hollowing out communities, rural, urban, suburban, rich and poor. And this was a drug addiction that came out of the medicine cabinet. In many instances it was a trusted professional in a white coat that was handing somebody this prescription saying this is going to do you good and it is not going to do you harm, driven by inadequate science, driven by frankly marketing scams. And that is inextricably related to this heroin issue. And so I think it is kind of hard to deal with the heroin issue in the abstract without talking about this culture of over-prescription, that hopefully we are working together to reel in.

Last question I want to ask—and it is probably too early to know this. But in terms of the growth of the number of hectares of poppy production in Mexico, do we have any evidence to suggest whether that is at all connected with marijuana legalization in the United States? I actually kind of like this notion of the States as labs and they can experiment and we can see what happens. But I have heard it said—and I do not know whether there is any evidence to back it up—that the legalization of marijuana in some States that has allowed marijuana to be grown has taken hectares of land that were used for marijuana cultivation and, well, we do not have a market for our marijuana anymore because there is competition, so we will switch to something like poppies to produce black tar heroin. Is there any evidence of that?

Mr. Chester. We have actually looked closely kind of at the crop transference to see if there is anything there, and I can tell you at this time, whether it is too early or whether it does not exist, we cannot definitively say that farmers have decided to switch from one crop to another in Mexico. We cannot say that with any degree of authority at this point.

Senator Kaine. But that is something that you are going to continue to monitor.

Mr. Chester. It is something that we do watch, yes.

Senator Kaine. Great.

Thanks, Mr. Chair.

Senator Rubio. To interject on that point, it is my sense—and you are both experts at this—that very few people wake up in the morning and say I am going to go shoot heroin just

for the first time. There is a gateway to the heroin use. A lot of it is being driven by people that were prescribed prescription opiates. They now become physically dependent. The prescription opiate is cut off. They are going through severe withdrawal, and the only thing that addresses that withdrawal, if they are not in treatment, is access to heroin, and that brings all sorts of problems.

Absent that, what is the other gateway? How does someone get dependent on heroin minus the prescription drug gateway, which we have already discussed?

Mr. CHESTER. Senator, it is a difficult question just because you are dealing with a number of variables down at the individual level as to the reasons why people engage in the behavior. We do know a couple things. Heroin in general terms is kind of at the end of a trajectory of long-term drug use and that a high number of heroin users are actually poly-drug users. And so they are not an exclusive heroin user. They get the drugs that are available to them, and because of the high availability of heroin, a lot of times that is heroin.

The other thing that we look at—and we do a number of surveys to look at this. But what we realize is that youth behavior from the ages of about 13 to about 18 is a very strong factor in terms of risk-taking behavior, in terms of underage drinking, tobacco, marijuana, things of that nature in shaping youth attitudes eventually that they carry with them for the rest of their lives in terms of risk-taking behavior for using other drugs.

So what we cannot say is that we can put a finger on this or that particular reason why a person does something, but we do know that the availability of drugs in society obviously increases the chances that an individual who is inclined to use them is going to intersect them at some particular point. And I think that is one of the—with the discussion we had about the availability of heroin being the driving factor.

Senator RUBIO. So just to understand your testimony, we understand the pill problem that leads to that. But what you are basically saying is if someone, especially at some point earlier in their life, begins to use a substance, alcohol, whatever it may be, an intoxicant of some sort, there now starts a potential trend where the next thing is, well, what is out there that is better, what is out there that is stronger. Once you have crossed that barrier, it could unleash this cycle of basically a set of dominoes that ultimately lead you to the heroin point.

Mr. CHESTER. Yes, sir. And again, it is not direct causation, but it certainly is risk-taking behavior and patterns of behavior.

And that is why the prevention strategies, particularly through programs like the Drug Free Communities Program that ONDCP manages are incredibly important because they are locally based, and they allow trusted individuals to be able to speak to people at very, very young ages about things just like that and their attitudes about drugs and foreign substances in the body and things of that nature. So they, through evidence-based prevention strategies, are able to talk to people at those young ages when they are vulnerable in shaping their ideas about drug use that they carry with them for the rest of their lives.

Senator RUBIO. Senator Markey?

Senator MARKEY. Thank you, Mr. Chairman, and thank you for this hearing. I think this is the most important hearing we are going to have on our relations with Mexico and with China this year in the Congress, and I thank you for it.

This issue of fentanyl is to my way of thinking kind of the most important threat that we have to families in the United States at this time. I will just give you some numbers. In Massachusetts, in 2015, 57 percent of the opioid-related overdose deaths in Massachusetts had a positive screen for fentanyl. Specifically of the 1,319 individuals whose deaths were

opioid-related in 2015 where a toxicology screen was available, 754 of them had a positive screen for fentanyl. So we can talk about prescription drugs. We can talk about heroin, but fentanyl is now the issue.

And we—that is, New England—are at the epicenter of it. It comes up from Mexico to Lawrence, Massachusetts, and then it goes out into New Hampshire, other States, but Massachusetts as well.

So the pathway is China into Mexico, then into Lawrence, Massachusetts, into Ohio, into Virginia, into Florida. And when it is over half of the deaths now in Massachusetts, it is clearly a looming threat that is a preview of coming attractions to every single city and town in our country.

So that is why this hearing is so important because it gets to the question of what is Mexico doing in partnership with China. We will start with that, Mr. Foote. What are specifically Mexico and China at the highest governmental levels doing in order to interdict this new synthetic formula that is lacing heroin with a drug 50 times more powerful than heroin, so powerful that the DEA does not even let its dogs any longer sniff for fentanyl for fear that the dog will just die with the first sniff of fentanyl. 3 grams, 3 equivalent of salt grams, could kill a human being if they gained access to it. What are Mexico and China doing in cooperation with you in order to interdict that drug?

Mr. FOOTE. Senator, first, I will touch on Mexico and China's bilateral relationship on this. With our support, Mexico and China are meeting and discussing fentanyl regularly every year. They are both involved in the multilateral side of things. Just last month at the U.N. General Assembly special session on drugs, they were both there. China—their minister of public security led the conclusion statement. They were fully on board. And they are a member, both countries, to the three international drug conventions.

We also sponsor in the United States two annual fentanyl and precursor chemical conferences with Mexico and China.

Senator MARKEY. So how successful is this effort so far?

Mr. FOOTE. That is a good question, Senator. Fentanyl is a new problem for the Department of State and INL, and it is one where we are applying lessons we have learned with other substances in other crime areas over the years, and at this point we are working as hard as we can to have success but I cannot quantify it.

Senator MARKEY. Has it been elevated to the highest level? In other words, with human rights and copyright infringement, is this issue now at the highest level of negotiations with the Chinese Government and with the Mexican Government?

Mr. FOOTE. It is. Mr. Chester went down in March with our folks and spoke to a large interagency group headed by the Attorney General in Mexico on this issue. We regularly engage with China. Our diplomats are going to China next week at a very high level diplomatic engagement where they will raise it. We raise it regularly in the joint liaison group on law enforcement, which has a counter-narcotics working group that meets throughout the year. We have actually seen some positive signs from China.

Senator MARKEY. What is the evidence? If you were going to convict them of doing something, what would the evidence be to convict them?

Mr. FOOTE. To convict?

Senator MARKEY. Convict China of actually doing something to block this from coming into Mexico and then into the United States. What would the evidence be to convict them of doing good?

Mr. FOOTE. Of doing good.

We have seen encouraging progress. There is still plenty to do. Last year, their ministry of public security officially controlled 116 new substances, including several analogs of fentanyl, and they have expressed high receptivity and continue to send information on new synthetic substances to help us to efficiently control them. So they are doing something. There is more that can be done, obviously.

Senator MARKEY. Clearly we have the evidence in 2015 in Massachusetts, and it is going to be worse this year in 2016. There is slim evidence that this thing is being slowed down. In fact, it is very clear that it is intensifying and it is going to kill. It is going to kill ultimately tens of thousands of Americans every year—every year. There is no other threat to our country that even matches that. Every single year, fentanyl is going to be able to do that. So if we do not stop it, it dwarfs every other issue. Every other issue will be a footnote compared to the magnitude of the impact on American families.

Mr. Chester, can we just go to Mexico? What is the level of cooperation that you are getting from the Mexican Government in interdicting fentanyl coming into the United States? We know it is el Chapo and his gang that is responsible for the traffic that comes up to Lawrence, Massachusetts, but pretty much for the whole country. What is your success level with the Mexican Government getting them to understand the magnitude of the threat to the American people?

Mr. CHESTER. Senator, I would tell you that I personally have been down there twice and then have dealt with the Mexican Embassy here in the United States. I will tell you that they understand how seriously we take this issue in the United States. They understand that this is our top illicit drug priority, and they also understand that it is not just heroin but it is heroin and it is fentanyl.

In a meeting down there in February, I put fentanyl on the table. And I will not say it was a “first heard” for them, but they were not really familiar with how serious the issue was in the United States. By the time we had gone down later with Director Botticelli and Ambassador Brownfield, that was part of the problem set that they agreed to work with us moving forward on.

So I will tell you that the Mexicans understand the importance that we place on this issue. They are very engaged on it, and they are willing to conduct a joint planning with us on the issues not only of poppy eradication, which addresses the heroin issue, but also lab identification and neutralization specifically on issues of either fentanyl creation or the milling of fentanyl with dilutants and other inert matter as it is transported across the border.

Senator MARKEY. Well, and it is a little bit disturbing to me if, from your testimony, it is a case of first impression for the principal law enforcement officials in Mexico, that they are just hearing about fentanyl, and it is just getting on their radar screen, and it is February of 2016, given the fact that more than half of all the people who died last year in Massachusetts, opioid-related, had fentanyl in their system. That is kind of a little bit disturbing to me. I am going to be very honest with you, and I do not like it to have just been introduced at that level.

I would like to have heard that President Obama has raised this issue with the president of Mexico, that President Obama has raised this issue with President Xi in China just because of the incredible level of fatalities all across our country. And we know specifically what the source of their death is.

So do you mind if I just continue a little bit? Thank you, Mr. Chairman.

So give me some hope here that there is an aggressive strategy in place on fentanyl and that it has been elevated to a level where there is a no-nonsense conversation going on in terms of what the expectations of our government is.

Mr. CHESTER. Right, Senator. In response to your concern, I know that the President did raise this with President Pena Nieto—the opioid issue with the Government of Mexico.

Senator MARKEY. He raised the fentanyl issue with——

Mr. CHESTER. I will check if it was specifically fentanyl, but I know the heroin issue was raised and the opioid issue——

Senator MARKEY. Well, I am asking about fentanyl here. Fentanyl is the epidemic. Fentanyl is the epidemic. It is not heroin. It is fentanyl. Fentanyl is 50 times more powerful. Fentanyl is what is showing up in a majority of the deaths. So you are not sure whether or not he has raised it.

Mr. CHESTER. And I need to make sure that fentanyl was part of that conversation between the two of them as well.

Senator MARKEY. How about you, Mr. Foote? Has the State Department specifically raised fentanyl at the highest levels with the Chinese Government and the Mexican Government?

Mr. FOOTE. We continue to raise it at the highest levels of dialogue that we have.

Senator MARKEY. What is the highest level?

Mr. FOOTE. Next week, our Deputy Secretary will be in China, and this is high on the agenda, if not top on the agenda. I cannot promise that President Obama raised it with President Xi, but certainly Secretary Kerry has raised it with the Chinese Government.

Senator MARKEY. Thank you, Mr. Chairman.

Senator RUBIO. Thank you.

Just a couple of points that I wanted to raise. First of all, why Lawrence, Massachusetts? Why New Hampshire? Why are these communities specifically targeted? In Florida, for example, central Florida, how does a community wind up targeted by these criminal gangs? What are the characteristics that are making them targets as opposed to some other part of the country?

Mr. CHESTER. Senator, there are a number of variables, one of which is the existing structure, the existing trafficker structure, that is in place in particular areas. In some cases, it is transportation networks. In some cases, the traffickers from Mexico have personal or business relationships with traffickers in a particular area or that geographically a place lends itself to further distribution. There are a lot of reasons why a particular——

Senator RUBIO. But the Northeast is far from the U.S.-Mexico border. I mean, my question is why did they not stop somewhere along I-95 and target there. Is it because of these existing structures that were there before?

Mr. CHESTER. We believe that there is very strong evidence that there are, that it is the existing structures that were there before.

When we specifically talk about fentanyl, one of the things that we have looked at as we have tracked the fentanyl crisis is why the Northeast, why the Eastern United States, why so much not the Western United States. And we believe that one of the strong contributing factors is the fact that fentanyl is more easily mixed into the white powder heroin which was preferred in the eastern part of the United States than it is in the black tar heroin which was preferred in the western part of the United States, and that has traditionally been the heroin market in the United States.

And so fentanyl is being mixed into powder heroin, and therefore it landed in the United States. And increasingly we are starting to see it be pressed into pill form and sold as counterfeit oxy or counterfeit opioids, but fentanyl has found a market in the Eastern United States probably because of those two reasons.

Senator RUBIO. I spent some time in New Hampshire over the last year and from that experience found myself in a lot of small townships, not large places, throughout New England that faced an overwhelming problem, almost as if they were specifically targeted perhaps because trafficking networks knew that they had smaller police departments. If you are a small township, you are not going to have a 1,000-officer department. Is there evidence that some of that is in play for these trafficking networks, that in essence, they look to set up in places where they can overwhelm local law enforcement with numbers and capabilities?

Mr. CHESTER. Senator, I do not know. I do not know whether the size of a population or the size of law enforcement was a particular reason why.

But to your point, it is a matter of deep concern that you find increasing numbers of heroin or fentanyl users in rural areas who are starting to use the product alone, and they are far from treatment and they tend to be further from first responders. Those are all things that make this particular crisis particularly pernicious. It is the fact that it has moved into a lot of rural areas, which is not something that we have seen in previous outbreaks of heroin or—

Senator RUBIO. And I know what I am asking—and perhaps it is more appropriate to the second panel—is more of a domestic issue as opposed to a transnational one. But some of the stuff we used to hear—because the supply is also driving the demand. They are interrelated. In essence, the supply meant these traffickers, who now had the supply on their hands, had to be more aggressive in finding market share. And one of the things I kept hearing a lot were that they were specifically targeting treatment centers, especially outpatient treatment centers where they knew people were getting treatment because of addiction, and they were waiting for them outside to tempt them to buy, that they specifically were targeting recovering individuals for the sale of this. And this is a pernicious, disgusting industry that we are dealing with here.

In that realm, I wanted to ask—you know, since the arrest of el Chapo, Secretary Foote, this is part of Mexico's, I believe, concerted policy to conduct high profile arrests of drug lords. And while it is positive that these organizations are being decapitated, have we seen any evidence that the arrest of a high profile individual impacts the ability of these organizations to continue to function specifically since el Chapo's arrest? Is there any evidence that the operation has been impacted by it, or is it just one of those things that is now functioning the way a corporate entity would, irrespective of who is at the top?

Mr. FOOTE. Senator, my personal experience is far more robust with Colombia where I led our programs several years ago. We have seen where the kingpin being arrested does certainly affect an organization. The question is how big is the structure, how organized is it, and how quickly can it recover. That is a question far better posed to our Drug Enforcement Administration guys than State.

Senator RUBIO. Let me ask you about Colombia. It is not directly related to the opiate issue, but nonetheless cocaine. They suspended their aerial eradication program ostensibly for fear of the impact that the defoliants would have on the population environmentally. There is a counter-argument out there that some have made, in which I find some credibility, that this is also part of the peace process, that in essence, this deforestation effort and the eradication effort was an irritant in the peace process with the FARC and other elements.

As a result, we now see numbers where for the first time in a long time there has been a massive increase in the amount of cocaine production in parts of Colombia that we had not seen in a while, and the assumption is that that cocaine is going to get sold. It is going to go somewhere and that we should expect at some point within the next couple years to see a spike in cocaine sales in the United States.

Do you have a view, irrespective of the reason why they are doing it, of what these new numbers mean for the U.S. in the years to come?

Mr. FOOTE. We are concerned about the suspension of aerial eradication. It is a sovereign decision of President Santos and the Colombian Government obviously. We believe while eradication and aerial eradication are not magic pills, they are valuable tools in any supply-side intervention on narcotics. It has long been a big part of our strategy in Colombia. We continue to work closely with the Colombians on the successor to Plan Colombia, which is Paz Colombia, Peace Colombia, and are in close contact to see which direction they decide to go if and when President Santos gets the peace process resolved.

Senator RUBIO. And here is my final question for the panel. And I thank you both for being here and for your testimony and for your work. The work you do is important and difficult.

We now have two separate but interrelated problems, as the Senators just pointed out a moment ago, the production of synthetic fentanyl, the growth of opiate poppies. My understanding is that the amount of poppy-based opiates grown in the western hemisphere is a small percentage of the overall production in the world. In your view—or do you know this—if a poppy-based opiate is produced or fentanyl is produced somewhere in the western hemisphere, Mexico or anywhere else, what percentage of that is destined for the United States in particular?

Mr. CHESTER. Senator, we believe that Mexico is the primary supplier of heroin to the United States and that the United States is the primary customer for Mexican heroin. That relationship in the western hemisphere is fairly solid. We do not see any widespread evidence of Southwest Asian heroin, Afghan heroin, Burmese heroin coming to the United States, although the Government of Canada does believe that Southwest Asia is its primary supplier of heroin.

So one of the things that we have discovered is a risk and we have identified as a risk is if we are successful against the Mexican drug trafficking organizations in bringing down the supply of Mexican heroin into the United States, do we open up the door for others.

Senator RUBIO. I think it is pretty clear that if you see a heroin overdose in the U.S., that heroin or that fentanyl came from Mexico or maybe in the case of fentanyl, China through the mail. I think that is pretty clear.

Here is my question. Are the opiates being grown or produced in the case of fentanyl in Mexico being sold anywhere else in the world or should we basically assume that virtually all of it that is being grown there—you can see it from the camera—pictures are being taken—all of that is headed to a city near you in the United States?

Mr. CHESTER. That is the assumption we make, Senator. Yes, that is correct.

Senator RUBIO. Well, I want to thank you both for being here. Did you have a final question, Senator Markey?

Senator MARKEY. Thank you so much. Again, for me this is the top topic. It does not get any bigger than this, and these are the gentlemen responsible for it in the United States. So

to have them here and to know that they are the principal people working on the fentanyl issue I think is absolutely central.

So let me just ask you this, Mr. Chester. Your title is Associate Director for the National Heroin Coordination Group. Do you think it is time for us to just change the name to the National Heroin and Fentanyl Coordination Group? Do you think we should change the name just so it advertises correctly what is going on to the American people?

Mr. CHESTER. Senator, when we began our work this fall as the Heroin Coordination Group, and after Director Botticelli stood up this group within ONDCP in order to provide focused efforts against the heroin and the fentanyl problem. In our work what we determined was that we were going to handle heroin and fentanyl as part of the same problem set for a lot of different reasons. What has evolved over time in our work and in our planning and our work with the interagency is that we have discovered the incredible importance of fentanyl more so than what was identified 6 or 8 or 9 months ago.

The other important thing about fentanyl that I would like to bring up is the fact that the emergence and the visibility of fentanyl is driven almost entirely by the postmortem testing that is done on individuals in overdose deaths around the country. And in those areas where the testing is done and fentanyl is tested as part of the toxicology panel, you begin to see more. So it leads us to believe that in looking at both the heroin and fentanyl problem, we have a significant fentanyl problem, as you identified, that we believe was being masked by this increased availability in heroin. So we handled both of them as part of the same problem set simply because it allows us to be able to deal with the trafficking and the supply chain and the effects on communities in the exact same way.

Senator MARKEY. No, I appreciate that. So that is what I am asking. Should we add fentanyl to your title in your opinion? Does that make sense given what you now know and given how little Mexico, it turns out, knows when you had the conversation in February of 2016 about fentanyl? They did not have it on their radar. Did we raise it so that they understand? The same thing is true for the Chinese. What do you think?

Mr. CHESTER. The issue being raised to the Chinese——

Senator MARKEY. No, no. I am talking about Mexico. I am talking specifically here about Mexico right now. They did not know in February.

And by the way, even when I say 57 percent, a lot of experts think that is an understated number because of the poor reporting that goes on in terms of the total number of deaths.

And by the way, it is no secret why they do it. It is like a 300 percent markup—300 percent markup—in terms of their ability to make money off this as opposed to heroin or other drugs.

So again, from my perspective, this is the issue. This dwarfs any terrorist threat to the United States. This is what is going to kill people, tens of thousands, ultimately hundreds of thousands of Americans. It is going to be this fentanyl that comes into our country. You are the front line on this. Mexico just heard about it. I am not sure the Chinese understand the priority that we expect them to deal with this issue.

Mr. Chester, earlier today in your testimony, you said that there are gaps in the interdiction of fentanyl from Mexico coming into the United States. Could you explain in more detail what those gaps are?

Mr. CHESTER. We are speaking primarily about gaps in our ability to be able to detect fentanyl at borders, and what was brought up earlier is the ability of canines, canines being trained in order to be able to detect fentanyl because it is so deadly.

And we work very closely with CBP both in terms of intelligence and in terms of policy to address those gaps to better detect fentanyl not only at the Southwest border but in our air freight locations in the United States whether it is U.S. Postal Service or whether it is a commercial company. That has been an area of ongoing discussion for us so that we can better determine how much fentanyl is getting into the country and to be able to detect it when it does arrive, and whether that is detecting the chemical, the fentanyl itself, or the dilutant with which it is mixed.

Senator RUBIO. Gentlemen, I apologize. We have got to move to the next panel because in about 45 minutes, I have to preside over the floor and I turn into a pumpkin here. Not literally. [Laughter.]

Senator MARKEY. If I may just conclude. I would just strongly recommend to the administration that when the President meets with the president of Canada and Mexico, that he raises fentanyl to the highest level with them and lets them know that that is a threat to our country. And the same thing is true in any communications with the Chinese Government that it has to be at the highest level.

Thank you, Mr. Chairman.

Senator RUBIO. Thank you, Senator Markey. This is an important issue in the Northeast and for the country.

And I thank you both.

We are going to welcome our next panel.

As we will say at the end of the hearing, we keep the record open for a few days. If you receive any questions in writing, if you would respond as quickly as possible so we can close the record. We thank you both for being here.

So as they are getting seated and situated, I am going to, once again, reintroduce the members of our second panel. The Honorable Teresa Jacobs is the Mayor of Orange County, Florida, which we hope, if it has not yet been finalized, will be the site of the Pro Bowl in 2017. Right?

Ms. JACOBS. Yes, it is.

Senator RUBIO. Maybe you can give us an update on that too. We are excited about it.

And, of course, Mr. Steven Dudley, who is the Co-Director of In-Sight Crime.

Mayor, if you are ready—your testimony has been submitted in writing, and we look forward to hearing you as well. Thank you for being here.

STATEMENT OF HON. TERESA JACOBS, MAYOR OF ORANGE COUNTY, FLORIDA

Ms. JACOBS. Thank you, Chairman Rubio. And thank you for calling this very important hearing and allowing me to share a local perspective. The conversation this morning has certainly been informative for me, as I am sure it has been for everyone here.

First, a little background on Orange County, nothing that you do not know, but for the record. Orange County is home to the City of Orlando and 12 other municipalities. We have a strong economy and an exceptional quality of life. We have a population of 1.2 million people that call Orlando home, but we also have 66 million visitors on an annual basis and we continue to shatter national records for tourism. That is the good news.

The bad news and the very sad news is that we, like too many other communities across this country, have seen an alarming increase in the number of heroin overdoses and related deaths. I say heroin. When I say heroin, I mean opioids, opiates, I mean fentanyl, all of them combined. Last year, we lost 85 lives to heroin. We lost 62 lives to fentanyl.

We have heard this morning testimony about the increase in deaths related to opioids and opiates of anywhere from 200 to 400 percent since 2007. In Orange County, we have had a staggering 600 percent increase since 2011 alone, and already this year we have had 90 reported opioid overdoses, about 1 in 10 resulting in death.

Florida's fight against this current wave of opioid addiction began about 5 years ago. You may recall that in 2010, Florida was known as the "pill mill capital" of the country. Florida practitioners were prescribing oxycodone at levels that exceeded all the other States in our Nation combined. At a State and local level, we responded by outlawing unauthorized pain clinics. Yet, today the battlefield has moved. Today we fight heroin. Today we fight fentanyl.

Given the dramatic rise in the flow of heroin and fentanyl into our community, one can only surmise that drug cartels perceived us as a ripe marketplace. Unfortunately, it is nearly impossible to accurately assess the size of the heroin threat in Florida and across States in our Nation. But there are a few things that we do know.

In Orange County, we know that last year approximately 2,000 heroin users moved through our county jail alone, and on any given day, we treat roughly 200 heroin addicts in our jail. We know that in 2015 our county jail housed 100 expectant mothers who were addicted, whose babies will most certainly be born tragically addicted to heroin. We know that over 60 percent of overdose patients are uninsured, and yet we have only one inpatient facility with 26 detox beds available to the uninsured for all four counties in our region, with a combined population of 2.5 million people. Simply put, we know that our county jail has become the treatment center of last resort for far too many people who find themselves addicted to heroin, fentanyl, and other opiates and opioids.

For the good of our citizens, we are fighting back, and here is how. Last summer, we convened the Orange County Heroin Task Force, chaired by myself and our sheriff. Our joint work is having a positive impact, including the passage of the 2016 Florida legislature, which passed a measure allowing naloxone sales without an individual prescription. And while there is no single cure or solution, we know there are some universally effective approaches, many of which have been discussed here today. But I think at the heart of it is that we have to recognize that we must address the demand side while we attack the supply side, and an either/or policy simply will not work.

On the demand side, through our task force, we have joined forces with our K through 12 public education system, our universities, our faith-based communities, our medical communities. Together we are launching a social media campaign to educate the public on the risks of this highly addictive and deadly drug. We are trying to convince our citizens and warn them in advance that this is something that they want to avoid at all costs.

We are also not only treating heroin addicts in our jail, we are implementing a new medically assisted treatment program using Vivitrol. And this is an option for all of our addicts that are leaving our jail.

But we need the Federal Government's help to treat more addicts. As I mentioned a few minutes ago, we are woefully short on beds and other resources.

On the supply side, we are also doing our best to arrest traffickers on our streets. But our local efforts, no matter how highly leveraged and coordinated, are simply no match for the

drug cartels and organized traffickers coming across our country's borders. And that is why we need your help to help stop the influx of drugs across our borders.

To end the crisis, to save lives, to save communities, we each have a role to play. Local governments have a crucial role to play. The State government does and the Federal Government does. But the efforts need to expand beyond government. We need every citizen that is a mother or a father or a friend of an addict—we need our entire communities engaged. We need doctors. We need the clergy. We need counselors. We need teachers. We need all of them to be informed. And that is why I think that we also need a nationwide awareness campaign.

And we have talked briefly about fentanyl. It needs to include the high risk of fentanyl and the low cost. Quite frankly, today it is less expensive for many of our addicts to get high on opioids than it is for them to go and get a Happy Meal. That is a sad state of reality that has to be addressed.

Thank you again so much for this opportunity, Mr. Chairman. Thank you for your and your committee's continued service and leadership on this issue.

[Ms. Jacobs's prepared statement is located in the Additional Material Submitted for the Record section at the end of this transcript.]

Senator RUBIO. Thank you, Mayor, and thank you for your work on this. You have been involved in this for a while now trying to deal with it back when the pill mill problem was going on, and we will talk about that in the questioning section.

Mr. Dudley, thank you for being here. We look forward to your testimony.

STATEMENT OF STEVEN DUDLEY, CO-DIRECTOR, INSIGHT CRIME, WASHINGTON, D.C.

Mr. DUDLEY. Thank you very much, Chairman Rubio.

As we know, as U.S. consumption of heroin has increased significantly in the last few years, the U.S. portion of the world heroin market is quite small by comparison in terms of users but really outsized in terms of potential earnings. The RAND Corporation estimated in 2014 that U.S. consumers spent as much as \$27 billion on heroin each year, an increase from \$20 billion in the year 2000.

Mexican, Guatemalan, and Colombian criminal organizations have reacted to these changes by producing more heroin.

As noted already in the earlier panel, Mexico accounts for the bulk of the poppy production in the region.

Seizure data of heroin along the southwest border also indicate that Mexican criminal groups are moving increasing amounts of heroin into the U.S. market. Mexican criminal organizations are also the key transporters of Colombian heroin to the United States, and they manage and purchase the heroin produced in Guatemala or buy the opium gum wholesale to process it into heroin themselves in Mexico.

Inside the U.S., the trend appears to be the same. The DEA says that Mexican groups are seeking an increasing amount of the market share in the distribution business itself, displacing other wholesalers.

In sum, the picture we have is one of an increasingly lucrative, vertically integrated market with large Mexican criminal organizations managing the product from the point of production to the point of sale and seeking a greater market share of these sales.

The reality of the supply chain, however, is much more complex. While it helps us to use well-worn monikers when talking about these organizations, the truth is that they are not nearly as strong or monolithic as they once were. Names such as the Tijuana Cartel, the Juarez Cartel, the Zetas, or La Familia Michoacana may still evoke fear and sometimes awe, but they are not organizations as much as brand names. In many cases, the individual parts of the organization have as much contact with the bosses as a local Coca-Cola bottling plant manager might have with corporate headquarters.

Even the vaunted Sinaloa Cartel is more horizontally than vertically integrated. Take the recent case of the Flores brothers in Chicago. Before they were arrested, Pedro and Margarito Flores were said to be Sinaloa Cartel distributors in Chicago, one of the areas of greatest interest to this subcommittee. And they were. But as Federal intercepts of their conversations with cartel leaders show, the two brothers negotiated independently with each of the top two members of the Sinaloa criminal organization, obtaining different prices for the product that they were selling. Even after a war started between the Sinaloa Cartel and a rival group called the Beltran Leyva Organization, the Flores brothers continued to purchase drugs from portions of the Beltran Leyva organization and the Sinaloa Cartel.

The Flores case cuts at two different myths about the Sinaloa Cartel: number one, that this is one single organization; and number two, that it is tightly controlled by a single leader or a single group of leaders. The point is that as shipments get further and further from Mexico's wholesale points, the loyalties become more disperse and in some cases completely disappear. This is especially true in the U.S. market where violence is not a viable long-term option to ensure loyalty, win market share, or become a monopoly.

The effectiveness of U.S. law enforcement has made violence terrible for business and made the distribution chain a more democratic, capitalist affair. This is evident in other ways as well. While the amount of seizures indicates that there is more heroin available in the United States, it is still moved in very small quantities. The median seizure for the Los Angeles Field Division of the DEA in 2014, for example, was a single kilogram. In Denver, a 10- to 12-pound shipment is considered large.

The case of the Laredo brothers, recently indicted in the Eastern District of Pennsylvania, is indicative of these trends. The Laredo brothers are charged with moving 1 ton of heroin over a 6-year period. This is about 14 kilos per month. The organization was so subtle and, as one Mexican analyst put it, "mom-and-pop," the Mexican authorities were not even aware of the group.

This brings us to Mexico. The horizontal nature of the distribution chain makes it a difficult law enforcement problem in Mexico as well. As noted, the once monolithic criminal organizations are shells of what they once were. This is in part due to infighting of the type mentioned earlier but also Mexican law enforcement efforts. Many of the fragmented pieces have formed their own criminal organizations and brand names.

The upshot is that the chain of production in Mexico is broken into numerous pieces, including small and large producers of opium poppy plants, the opium gum producers, and processors, the wholesale purchasers, and the transporters. Production, transport, and distribution may all be different organizations. The Laredo brothers, for example, were purchasing opium gum from an independent broker, then processing it themselves, and

distributing it in those small quantities in the U.S. for years without running into trouble with the large, supposedly all-controlling Sinaloa Cartel.

To be sure, violence is still a viable option in Mexico, so the pendulum may swing back towards more monolithic criminal organizations. But for the moment, the reality is that there are literally dozens of small criminal organizations involved in this trade from the point of production to the point of sale.

In sum, while the level of control that the Mexican production and transport groups exert over the supply chain is clear, we are not talking about one or two criminal groups, but dozens of interlocking organizations whose alliances are constantly shifting. The heroin supply chain appears to be a largely horizontal, diversified operation with multiple actors, and one that is obedient to market forces rather than one or two single vertically integrated distributors.

The result is that law enforcement efforts are largely muted. Whether you debilitate the Sinaloa Cartel or the Laredo brothers, you are hindering a small part of the overall production and distribution chain. Even if you did slow the heroin from Mexico, you would face an insurmountable task: stopping the flow from other countries, which would undoubtedly fill the void and account for the bulk of worldwide production anyway. Canada already gets up to 90 percent of its heroin from Afghanistan. And the United States once got all of its heroin from the Asian markets that supply the rest of the world.

Thank you for your time and attention. I look forward to your questions.

[Mr. Dudley's prepared statement is located in the Additional Material Submitted for the Record section at the end of this transcript.]

Senator RUBIO. Thank you both for being here.

I want to begin with one of the questions I alluded during the testimony, and that is—I cannot prove it. I guess it is anecdotal. We do not have a number behind this. But the notion that these criminal groups are specifically targeting people recovering. In essence, they basically station themselves outside of a rehabilitation outpatient center, even an inpatient center, knowing that these people are vulnerable and enticing them to fall back into addiction.

Mayor, have you seen evidence of this? Mr. Dudley, have you heard about this as a recurring issue, a specific practice at the local level of targeting people in recovery for sales?

Ms. JACOBS. Senator, I have not seen evidence of targeting our treatment facilities.

I will say that it certainly appears on the surface that there has been a targeting effort towards which communities to infiltrate with heroin, and certainly I look to the increase in heroin coming into our communities, the increase of fentanyl at the same time that we were restricting access to prescription drugs as suspecting that there is a strong correlation between those two and a causation between those as well. But I do not have direct evidence of it. It just seems hard to imagine that there would not be a direct relationship between them.

Mr. DUDLEY. Thank you, Senator.

I also do not have direct evidence of this activity on a local level. I will say in Mexico that criminal groups have targeted recovery facilities, but more as recruitment centers, not necessarily—— Senator RUBIO. Recruitment centers for?

Mr. DUDLEY. Recruitment centers for them, to basically build out their own criminal operations.

Senator RUBIO. You mean for like dealers?

Mr. DUDLEY. Not for dealers. Just for membership. So people who would participate in the criminal organization. So that has certainly happened especially with regard to La Familia Michoacana, a very famous group there.

The upshot of this is to say whether or not they are targeting to pushing drugs in certain areas I am not sure is as relevant as this sort of whole picture, which is what the Mayor alluded to, which is this idea that this is largely driven from people who use pharmaceutical drugs, and those people you can find all over. And that accounts also for the sort of dispersed nature of this epidemic as opposed to sort of the 1970s where you had it very concentrated in urban areas. Now we have it spread out throughout many different parts of the United States.

Senator RUBIO. So I want to share with you an anecdote. This weekend, I have a personal friend who is a police officer in Miami Dade County, and he recounted a story that he pulled up to a car that was kind of pulled over on the side of the road. And there was a woman in the driver's seat. She was kind of slumped over, and it caught his curiosity. So he pulled over and knocked on the window. This was a nice car, by the way. Obviously, this is a person of financial means. Knocks on the window and the person immediately pops to attention. And he can see that in her arm there was a needle. She was basically shooting up on the side of the road in a luxury vehicle. Knocks on the window. She rolls down the window. They begin to interact. Obviously, he had a decision to make about how to treat her. This is someone who said 10 years ago he would have arrested her and taken her in as a criminal using drugs in the street.

Today his perception has changed because he has had several interactions, including this interaction with a person who, by the way, is a member of the Florida Bar, is a successful, functional attorney whose husband apparently also has a problem. The fundamental challenge he faces: he does not want to take her to jail. He does not view her as a criminal. He views her as someone who has a disease and is in need of treatment to overcome it.

And by the way, her gateway into heroin was the use of a pharmaceutical pain killer for a surgical procedure 6 or 7 years ago, which she lost access to the medicine, and this is what has happened.

And so the concern that I have is twofold, and perhaps you can both opine on this.

Number one, if today you are dependent upon an opiate substance, irrespective of how you got there, but let us say in the case of this person because of the use of a pharmaceutical that led to this point, there is still an extraordinary stigma associated with it as if you are a bad person who is doing a really bad thing and needs to be punished for it.

And second, even if that stigma were to change so that we can get more people into treatment and accepting the fact that I am physically dependent on this substance, in many communities there is nowhere to take them. The only place you can take them potentially is to a jail where you hope their withdrawals are managed but may not be. And in essence, there is nowhere for them to go. We have many places. We just do not have the capacity to meet that reality.

Which leads to the third problem, and that is the number of people who end up in a jail cell for 15 days, go through withdrawal, do not realize they have lost their tolerance, even in that short period of time, and when they fall off the proverbial wagon, they go back to using the levels they were using before they went through withdrawal and it kills them because they lost their tolerance for an opiate.

So given that perspective, I am sure there are hundreds, if not thousand of cases like that. What are the impediments to getting someone who faces this now who—I do not think so, but

could be watching C-SPAN at this very moment. Not many people watch C-SPAN—but are watching this or are hearing us talk about this. What is out there today or what is missing for someone who needs this treatment and just does not know what to do about it next? Because especially for the uninsured, there are not very many options from my understanding.

Ms. JACOBS. Thank you, Mr. Chairman. I think that is a key part of addressing the demand side. Part of it is to educate people and help them make the right choices to avoid overuse of prescription drugs, but the other part is how do we provide the resources to treat people that are addicted. And the treatment options are very limited. For the uninsured, as I pointed out, 26 beds for 2.4 million people. Our jail alone, one out of four jails in the region, we have on average 200 people that we are treating for withdrawal symptoms and offering them a treatment program when they leave. We need more treatment facilities.

When you ask me the question are traffickers, are dealers preying on people coming out of treatment centers, the reality is we do not have enough treatment centers to prey on.

Senator RUBIO. You said in your testimony—and I do not want to interrupt, but you said in your testimony you believe that Florida was specifically targeted because they knew we had the pill mill problem, and once that was cut off, these folks were going to need—

Ms. JACOBS. Exactly. That is what I believe. I do not have empirical evidence. What I have is the evidence of the increase in the flow of heroin and the increases in deaths related to heroin in correlation to our cutting off the pill mills.

Let me also say that while we were dispensing more oxycodone than the rest of the country combined out of Florida, most of that was leaving our State. And most of these pill mills—you could drive up and you could look in the parking lots. The parking lot would be full and only a small percentage of those were local license plates. So the cartels may have misjudged the appetite, but they, no question, have flooded us with very, very cheap drugs.

And the number of youth that I have seen that are struggling with addiction and have turned the corner and have had the good fortune and the money to find treatment, the insured portion of that population, to see that there actually is life after heroin addiction is very encouraging. But what is very discouraging is that most people that are addicts have no idea there is life, and most people that are addicts have no opportunity to get to those treatment centers.

Senator RUBIO. Just to fill in the gaps for those who may not be fully aware of the Florida pill mill problem, we had these facilities. You just basically pulled up and said my neck hurts or my back hurts, and by routine, they would give you a package of prescriptions. It was not just, by the way, oxy. They also put some other stuff in there. And people knew this, and you would have busloads of people actually come in sometimes. It was a huge problem. The Florida legislature closed that loophole that was allowing this to happen. So just to be fair, we are not talking about the oxy prescriptions being driven by a doctor at his or her office. It was these specific facilities that drove it.

Did you want to add something on the treatment part of it? Because I had one more question. I know that Senator Kaine—

Mr. DUDLEY. Just very quickly. I mean, this is obviously framed as a law enforcement debate. And certainly I was asked to talk about the criminal organizations.

But as you rightly pointed out, this is a public health issue. At the heart of it, this is a pharmaceutically driven epidemic, and it is a public health issue. And that is really the difficulty in facing up to this is that it is not necessarily strictly law enforcement. We are not

talking about throwing people into jails. We need to be talking about how to get them better treatment.

Senator RUBIO. And my sense on the human side of it is I do not believe anyone wakes up in the morning and says today is the day I become a heroin addict or an opiate addict. It is not something somebody wants to happen. You just see growing evidence. People do not realize the power of this. There is no responsible way to use this, and its impact on everybody is a little different. We know some people are more sensitive or susceptible to addiction than others, but it basically restructures the brain's chemistry in a way a disease would and it has to be treated as that.

I look at these statistics, for example, in Florida as just an example. Orlando had 83 heroin deaths in 2014. Other communities have large numbers with West Palm Beach at 51, Miami at 60, Sarasota at 55. But that number pops out at you as a place that has been specifically targeted.

And then you see the rise in deaths and kind of the spike we have seen across the country in heroin and opiate deaths where the takeoff point is the introduction of fentanyl which, as we have already seen from testimony today, is an incredibly powerful and lethal substance, which in fact from my understanding is not prescribed outside of a hospital setting to begin with on the pharmaceutical side and is now being laced into——

I want to go to Senator Kaine. So I wanted to leave with this thought. I read the other day a report where someone who was a former—he is now a recovering addict—was asked about this and said, you know, when you hear that someone has died from an overdose that was sold by a particular dealer, it makes you want to buy from that particular dealer because you know what they are selling is the strong stuff. Now, maybe that is just one interview, one line somebody said. But it just kind of tells you the point we have reached here where it is a very difficult and debilitating condition that we have to try to understand here. And I think one of the keys is to remove the stigma associated with it.

And I think many of us would be very surprised at the number of people we interact with on a daily basis that at some level have a dependence problem, maybe not through street heroin, but of some sort as a result of what we have seen happen in this country. And hopefully we can make advances in pharmaceuticals so that we can draw the line and we will be able to treat pain effectively in this country without putting people at risk.

Senator Kaine?

Senator KAINE. Thank you, Mr. Chair.

And thanks to each of you. I am sorry I missed your opening testimony, although I read your written testimony.

And, Mayor, I will start with you. I was a mayor too in Richmond. And it was only when I was mayor that I really fully grasped the depths of the demand side of this challenge. You know, you can arrest a dealer and arrest another dealer and arrest another dealer, but if the demand for drugs is so potent, if it has its hooks in people so deeply, the next dealer will appear tomorrow.

We had a really tough problem in Richmond, and a lot of drug-related homicides were taking place in this little neighborhood near where the church that I go to is. And the number of stories that would appear on the front page of the paper about somebody from the suburbs coming in to buy drugs and getting shot at the corner of 2nd and Maryland or wherever, and you would think about five of those stories, people would quit driving in to buy drugs there. But, no, they would keep driving in to buy drugs.

And that just was evidence of how powerful addiction is, that you would have all this objective evidence that, wow, this is really going to be dangerous for me to go, but much less that the drugs could be dangerous, I could get shot, but the need is so intense that I am still going to go. And it sounds like you have seen that in your community. I was a mayor 20 years ago. The drugs were different. But it is the same thing of this addiction. And that is why the treatment issues are so important.

And the other thing we used to hear anecdotally—I am not an expert in this field, but when somebody who is under the grip of an addiction says I want treatment, that is a window that opens where the treatment, if it is not there, the window can close. And in a month from now when the bed opens up, the individual may be past the point of wanting treatment, may have ODED or may have lapsed back into behaviors not desiring treatment. So I do appreciate what the chair was saying and you were saying too about the need for treatment.

I am curious if you can talk about as a mayor the way to solve some of these challenges is definitely through how the partnership, State, Federal—talk a little bit about what you have done in your county on the partnership side. Do you have the right stakeholders around the table? Are there things we can do from a Federal level to ensure that if we are issuing funds, that we do it in a way that requires regional cooperation or multi-level stakeholder cooperation?

Ms. JACOBS. Thank you, Senator. In Orlando, one of the things that I think we have done very effectively is regional cooperation and collaboration. I think that that is crucial on tackling any large issue such as this. And so one of the reasons that we pulled together the task force that we did is we brought in so many different disciplines to make sure that we could attack this problem from all angles.

It is so important. We have limited resources at all government levels, and it always seems like the demand for resources outpaces supply. So it is important that programs are structured in a way that the funding is put to its best use.

And I do think that collaborative effort is important. We have a Metropolitan Bureau of Investigation that pulls together our FDLE, FDA, our local law enforcement, our police officers, our sheriff, our State attorney's office. That has been very effective for us on the enforcement side of this.

In terms of your comments about that window of opportunity for addicts, I cannot understand it either because I have never experienced a feeling of needing something so badly that I am willing to risk my life to have it. But I do understand that is the reality. I know enough people. Once we formed the task force, enough people came forward, literally walked up to me on the street. You know what it is like being a local mayor. People recognize you. They come up and they pour their heart and soul out to you. And it is a blessing to be at that level where you can really heard firsthand. And I have seen young people that you would never in your wildest imagination have thought were heroin addicts tell me their stories.

And what I also saw—I think I mentioned before you walked in here—was I also saw the other side. I saw that they came out the other side of heroin addiction, and they are living full lives and they are getting college degrees and they are going to be productive members of society.

And I think that most heroin addicts do not believe that is a possibility, and if they have that moment, if it is 15 minutes, if it is 2 hours, if it is 2 days, where they say, gosh, I want to kick this, reality is they are not going to be waiting for 2 weeks or a month. They are going to

be waiting a lot longer in most of our communities to get into a treatment facility unless they have got a substantial amount of money. And that is a huge problem.

And as I said in my testimony, the best option is our county jail right now, and that is a lousy option. Not to say we have a bad jail. We do our best. But having a record does not help the situation.

So we really need to have options available. We need to have education. We need to have hope. We need to have whole communities that are engaged. And as you point out, it is destroying more than lives. It is destroying entire communities.

Thank you, sir.

Senator Kaine. We had, Mr. Chair, a chart recently placed before us at another hearing about opioid-based ODs per capita, the 50 States arrayed. It was unlike any chart I have ever seen ever. If you look at a chart that is usually about some kind of problem or crime or social breakdown, high income States will be at one part of the chart and low income States will be at the other part of the chart. If you looked at the top 10 most affected States, they included some of the poorest States in the country and some of the richest States in the country. And if you looked at the bottom 10 affected States, they included some of the poorest States in the country and some of the richest States in the country. This is really unlike any sort of similar epidemic or law enforcement problem I have ever seen in the traditional demographic data, not at all a predictor. It is rural over the suburban. It is all regions.

I went to a drug court graduation. Kind of the founding drug court in Virginia is in the Roanoke area, and the judge who founded it, who was this super, farsighted thinker about the need for drug courts, had a child who many years later was killed in a drug-related incident. And after I spoke at the graduation, one of the probation officers who helps the court run and has done so as a spectacular advocate for many years came up to me and said this is my second drug court graduation this week. I said, did you have another class? He said no. I went to my son's graduation in a community about 2 hours from here.

This affects every level, and that is why we are now spending the time that we are. But we have not spent time in this committee on it, and it is really important that we do so because this is not—just like it does not have demographic borders, this is not a problem that even has national borders. And we have got to grab a hold of some of the dimensions, Mexico, China, the other nations that are experiencing this, and build those partnerships not even in a metropolitan region, but we have got to build law enforcement and other partnerships internationally.

Thank you for being here, for your testimony.

Thank you, Mr. Chair.

Senator Rubio. Thank you, Senator.

And I just wanted to ask you, Mr. Dudley, about these transnational groups that are targeting us. I think in your testimony you talked about this. So I just want to reiterate it. Whether it is fentanyl being produced synthetically or poppy-based opiates being grown in the Western Hemisphere, in particular in Mexico, they are coming here. This is the almost exclusive market for these trafficking networks. Is that correct?

Mr. Dudley. That is correct, absolutely. There is a small market, local market that they can satisfy, but it is minimal.

Senator Rubio. Because you would think—so logically they are crossing the border, you would think the easiest from a logistical point of view is for them to flood it into Texas or flood it into California or into a border State. But you are hearing where the outbreaks are.

And this is a national problem. There is no community in the country that does face it to some level, but you see these outbreaks in the Northeast in New Hampshire and Massachusetts and in places like central Florida. So it is not even I-10 alone where you would think they would come across.

What is your view of how is it winding up in these pockets? What are the distinguishing characteristics? You heard the previous testimony of the government witnesses. What in your view are the distinguishing characteristics that turn a community into a high- propensity, high-risk area?

Mr. DUDLEY. You know, it is such a new phenomenon because it is so disperse. But the fact that it is so disperse is really what leads to the criminal organizations being so disperse. And the notion that we have one single, all-encompassing enemy that is called the Sinaloa Cartel and once we incarcerate Chapo Guzman, then everything will be resolved is just simply not correct just because of the disperse nature of the market and the way in which these criminal organizations will satisfy that market.

It is an odd thing because in a way there are certain elements of this epidemic that we are victims of our own success. The fact that you would create ways so you cannot tamper with OxyContin, for example, you cannot store it anymore, the way in which it is distributed, well, then that makes it less available to people so then they start to search out other things.

The way in which the Mexican Government, in conjunction with the United States Government, has captured or killed several of the larger leaders of the larger criminal organizations has led to a fragmentation of these groups. So you have groups like you referred to Guerrero earlier. There is a Guerrero Unidos group, which was the group responsible for the massacre or supposed massacre of those 43 students that disappeared, 43 students currently still. You know, this is a group that was an offshoot of a larger group, the Beltran Leyva organization, and there are several like them.

So in order to wrap your hands around this as a law enforcement issue, it is incredibly difficult because the terrain is so much more horizontal than vertical. And even when you take out the larger leaders, what you are left with is a fragmented criminal landscape, and a landscape that does not necessarily—as in the cocaine market, they might depend on getting product from another country. In fact, they do from the Andes region. They need to get their product from other criminal organizations. But they do not have that dependency when it comes to the poppy production which is local and the heroin production which is local. So they can produce all of this themselves, which makes it much more difficult to wrap your hands around as well.

Senator RUBIO. Well, do you have anything further Senator?

I want to thank both of you for being here, for sitting through the previous testimony. I hope that was insightful as you go back and continue your work. And I want to thank you for coming here today and being a part of this hearing as well. This is an important issue. There has been a lot of debate about what is being done domestically on this issue. I am glad we touched on it.

I think this has to be dealt with. There is not like one law we can pass that deals with this. It has to be dealt with comprehensively whether it is on the treatment side for people to recover, on the prevention side, but also by targeting these organizations who are in the business of murder basically, which is what this ultimately is, and not just murdering each other for territory, but the direct murder of Americans by targeting us with the distribution of these products in our country.

So I want to thank all of you for being here.

I also want to ask consent to enter a statement for the record of Jack Riley, who is the Acting Deputy Administrator of the Drug Enforcement Administration. And without objection, I show that ordered.

[Mr. Riley's statement is located in the Additional Material Submitted for the Record section at the end of this transcript.]

Senator RUBIO. The record for this hearing is going to remain open until the close of business on Tuesday, May 31st. You might receive some questions in writing. If possible, I would ask you to respond just so we can close the record on this.

And with that I thank you both for being here, and this meeting is adjourned.

[Whereupon, at 10:55 a.m., the hearing was adjourned.]

ADDITIONAL MATERIAL SUBMITTED FOR THE RECORD

Additional Questions Submitted for the Record by Members of the Committee, Responses to Questions Submitted to Assistant Secretary Daniel Foote by Senator Marco Rubio

Question 1. Mexico has been a very good partner but systemic corruption and other issues, including issues of trust, persist. What is the U.S. government's assessment of Mexico's commitment to truly stopping the Sinaloa cartel, in particular, and the flow of illicit narcotics to the U.S.?

Answer. Our partnership with the Government of Mexico on counternarcotics has led to enhanced collaboration on this important issue. The State Department's Bureau of International Narcotics and Law Enforcement Affairs (INL), under the Merida Initiative, is working with the Government of Mexico to help build the capacity of Mexico's law enforcement and rule of law institutions to disrupt drug trafficking organizations (DTOs) and to stop the flow of drugs from Mexico to the United States, including augmenting their ability to coordinate with U.S. law enforcement agencies. Through Merida, we have provided the Mexican government with the communications equipment and technical assistance to enable the Department of Homeland Security's Customs and Border Protection (CBP) and the Mexican Federal Police to conduct coordinated patrols of our shared border. Merida-supported implementation of the Cross Border Secure Communications Network and Cross Border Coordination Initiative provides direct communication between CBP Sector Offices and Mexico's Federal Police and State Command and Control Centers at ten locations along our shared border. INL also is working in partnership with CBP to provide training to Mexican Federal Police officers assigned to the northern border region.

The United States and Mexico are working to increase communication and information sharing on combating the production and trafficking of heroin and meth-amphetamine. In addition to discussions at the high level Security Cooperation Group meetings, in the last year INL supported U.S. Drug Enforcement Administration-led bimonthly counternarcotics meetings, which bring together experts from both countries to share information and strategies. These efforts to increase cooperation are paying off. Federal and state police in one

of Mexico's northern border states recently arrested two suspects and seized 630 kilograms of methamphetamine, 80 kilograms of heroin, 48 kilograms of cocaine, one semi-automatic weapon, and two AK-47 assault rifles after acting on real-time intelligence provided by U.S. law enforcement. The federal police unit involved in the operation participates in the bimonthly counternarcotics meetings.

In recent years, the Government of Mexico has taken active steps to reduce corruption and other illegal activities in police forces and government institutions by vetting public officials through its Control de Confianza system. INL seeks to strengthen and accredit Mexican vetting institutions by establishing and deploying uniform standards for polygraph administration, background (socio-economic) investigations, and psychological assessments.

Question 2. Mexico has adopted a policy of high profile arrest of drug lords. While it is positive that these organizations are being decapitated, has the drug trade run by the cartels been impacted by these arrests in the way envisioned?

Answer. Capturing and successfully prosecuting high profile traffickers who have committed serious crimes and have operated with relative impunity is essential to maintaining the rule of law. High profile drug lords are responsible for the deaths of tens of thousands, and their sophisticated organizations create violence, generate illegal earnings and influence, and ultimately harm U.S. citizens and interests through cross-border flows of illicit drugs, goods, and people. We refer you to the U.S. Drug Enforcement Administration for additional details on the potential impact on the drug trade resulting from Mexico's high profile arrests.

Recognizing, however, that targeting high profile traffickers alone will not solve Mexico's security dilemma, the State Department's Bureau of International Narcotics and Law Enforcement Affairs (INL) supports Mexico's security and law enforcement efforts more broadly. Combating transnational criminal organizations requires a comprehensive approach that disrupts illicit financial and trafficking networks, combats government corruption, strengthens the rule of law, bolsters judicial systems, and enhances transparency. Under the Merida Initiative, INL focuses not only on disrupting organized criminal groups, but on institutionalizing rule of law, strengthening border security, and building strong and resilient communities in Mexico. INL's efforts to enhance state-level law enforcement professionalization, support Mexico's efforts along its northern and southern borders, and assist Mexico's transition to an accusatory justice system all augment the capacity of Mexico to effectively provide security, disrupt organized crime, and manage its borders.

Question 3. Since the arrest of Joaquin "El Chapo" Guzman, has there been a noticeable drop in narcotics trafficked by his organization? Specifically heroin?

Answer. At this time, the effect of El Chapo's arrest on the amount of narcotics trafficked by the Sinaloa Cartel is unclear. We refer you to the U.S. Drug Enforcement Administration for additional information on shifts in the trafficking of narcotics, including heroin.

The United States is fully committed to working with Mexico to combat the production and trafficking of illicit drugs. Over the past year, our bilateral dialogue, specifically on heroin, has reached an unprecedented level of openness and coordination and we are continuing to work closely with Mexico to increase these efforts.

Question 4. What successes can the U.S. government point to in cooperation with the Mexican government that have yielded concrete results?

Answer. For the past eight years under the Merida Initiative, the U.S. government has worked closely with the Government of Mexico to advance our shared security objectives and these efforts are demonstrating results, including:

Criminal Intelligence and Analysis Program: To support the Government of Mexico in improving criminal investigations to hold drug traffickers and other criminals accountable and boost public confidence in the rule of law, INL is supporting the professionalization of criminal intelligence analysts throughout Mexico. Initial programming has focused on equipping and training analytic units along the Mexico- U.S. border to serve as the primary state-level liaison with U.S. law enforcement entities to develop intelligence related to drug cultivation and trafficking, extortions, kidnappings, and homicides.

INL has trained and equipped five analytic units that have contributed to 1,900 investigations/citizen complaints resulting in more than 200 arrests as of the end of 2015. The units in the cities of Chihuahua and Ciudad Juarez provided intelligence that led to the arrest of a principal leader of the Sinaloa cartel. The Chihuahua unit also assisted in the identification and apprehension of two suspects responsible for an attack on a Ciudad Juarez television station, in addition to six kidnappings and five homicides. This unit also aided the apprehension of suspects responsible for the murder of the sons of two prominent Mexican journalists. The Sonora unit developed tactical intelligence, which led to the arrest of four suspects, identified as former Mexican military and enforcers for the Sinaloa Cartel. It also worked with ICE/HSI on an investigation that resulted in the seizure of five weapons, one grenade, three vehicles, and 450 kilograms of marijuana in Nogales, Sonora in 2015.

Anti-Money Laundering: To assist Mexico in disrupting transnational criminal organizations (TCOs), INL provided over \$16 million in hardware, software, servers, and technical assistance to Mexico's Financial Intelligence Unit (UIF), a division of Mexico's Secretariat of Public Finance and Credit responsible for receiving, analyzing, and disseminating information on suspicious financial transactions. This assistance enhanced the Government of Mexico's ability to combat financial crimes and money laundering activity, resulting in the following successes:

In 2014 alone, the UIF froze 761 suspicious accounts.

Between March 2014 and May 2015, the UIF froze approximately \$41 million in suspicious assets.

The UIF reports it collected as much data in 2015 as in the previous six years combined due to new IT platforms and additional data storage capacity principally provided by INL.

Corrections: Since 2008, the Department of State's Bureau of International Narcotics and Law Enforcement Affairs (INL) and the Government of Mexico have partnered to create a more effective, transparent, and humane prison system, including through accreditation by the American Correctional Association (ACA), which has helped to reduce escapism and mitigate the ability of imprisoned cartel members to fuel organized crime from behind bars. As of May 2016, a total of 30 Mexican correctional facilities have achieved ACA accreditation: six federal prisons, 22 state prisons, one state central office, and the federal training academy. INL plans to work toward having all federal prisons and one quarter of state prisons ACA-accredited by 2021. In a recent National Human Rights Commission (CNDH) evaluation of more than 150 federal and state prisons, ACA-accredited prisons received significantly higher

average scores than non-ACA-accredited facilities. Of the top ten facilities, eight are either accredited or seeking accreditation, and none of the ten lowest scoring facilities in the CNDH evaluation are ACA-affiliated.

The state prison system in Chihuahua is an example of the program's success. In 2010, 216 prisoners in Chihuahua died as a result of prison violence, and the state reported more than 17 escapes. After achieving INL-sponsored ACA accreditation in 2013, there have been only three violent prison deaths, and no escapes from any accredited facility.

Question 5. I believe we should continue to expand military to military cooperation with the Mexican government as long as the Mexicans welcome our contributions. Maritime cooperation between our navies and coast guards seems like an underdeveloped area. Perhaps U.S. Northern Command should look at a role for Mexico to play in NORAD. The U.S. should also work to bring Canadian law enforcement into closer cooperation with Mexican law enforcement to stem illicit trafficking. What other opportunities exist where cooperation between the U.S. and Mexican governments can be improved?

Answer. We have an excellent relationship with the Mexican government and together we are continuously assessing our security relationship and working on ways to improve and enhance our cooperation.

The biannual "Security Cooperation Group" meeting, co-chaired by the National Security Council and Mexico's Center for Investigation and National Security (CISEN), serves as the primary forum for our senior policy makers to work with their Mexican counterparts to devise strategies to combat our shared security threats and identify and reassess strategic priorities, such as continuing the fight against organized crime, enhancing counternarcotics efforts, and jointly managing our 2,000 mile shared border. There are also multiple venues and working groups that facilitate operational and tactical security cooperation, including through the 21st Century Border Management Initiative, bilateral border violence prevention protocols, and other coordination mechanisms.

Specific to our military relationship, U.S. Northern Command works with Mexico on initiatives that not only assist in mitigating the current Transnational Criminal Organization (TCO) threat, but also focus on capacity building. They work with the Mexican Navy (SEMAR) and Army (SEDENA) to build specific capabilities, enhance our bilateral and regional engagement, and prioritize joint activities through programs in aviation, communications, and civil-military operations. SEMAR's participation in exercises, combined and multilateral, is increasing and planning is underway for joint U.S.-Mexican exercises next year that will increase interoperability with U.S. Naval Forces and bolster regional security.

The North American Leaders' Summit, to be attended by President Obama, Mexican President Peña Nieto, and Canadian Prime Minister Trudeau, will take place in Ottawa on June 29. The discussion of the effective exchange of information and coordination among law enforcement authorities will remain essential. We will also discuss continued coordination to pursue areas of cooperation to counter drug trafficking, trafficking in persons, and other illicit trade.

Question 6. Please summarize any progress that has been made as a result of the bilateral talks that have been occurring over the past year on how the U.S. and Mexican government can address heroin cultivation and production in Mexico.

Answer. Over the past year, our bilateral dialogue with the Government of Mexico on heroin has reached an unprecedented level of openness. This has led to enhanced U.S.-Mexico collaboration on this critically important issue, including increased communication and information sharing on heroin. In March 2016, Office of National Drug Control Policy Director Michael Botticelli and the State Department's Bureau of International Narcotics and Law Enforcement Affairs (INL) Assistant Secretary William R. Brownfield participated in meetings hosted by the Mexican Attorney General's Office with high-level officials from each of the Mexican federal government agencies involved in drug enforcement to discuss U.S.-Mexico collaboration on heroin and potential new areas of assistance. INL continues to increase the capacity of law enforcement and justice sector institutions to detect heroin distribution networks and prosecute those involved. INL has hosted seminars with several Mexican agencies to increase information sharing on heroin, and has facilitated a study trip with Mexican officials to Guatemala and Peru to examine poppy eradication best practices. The United States has provided more than \$130 million in non-intrusive inspection equipment, maintenance, technical assistance, and capacity building to enhance the capabilities of Mexican officials at internal checkpoints and points of entry along Mexico's northern and southern border. INL is also working with the U.S. Drug Enforcement Administration (DEA) to provide training to augment Mexico's ability to identify, investigate, and interdict clandestine heroin labs, and better prepare Mexican officials to dismantle them.

This year, the Government of Mexico is expected to finalize its National Drug Control Policy Plan, and to lay out protocols for poppy eradication. Mexico is also working with the United Nations Office on Drugs and Crime (UNODC) on a yield study that will enable more accurate estimates of potential heroin production. Initial reports outlining baseline poppy cultivation estimates will be completed this year. These reports will provide a greater understanding of how Mexican eradication and interdiction responsibilities will be organized going forward, and will help shape the best areas for U.S. assistance. INL will continue to work closely with Mexico to increase efforts to combat heroin.

Question 7. How would you assess the assertion made by a group of experts from the Inter-American Commission on Human Rights, that there may have been another bus involved in the incident in which 43 students disappeared in Guerrero, Mexico, that was packed with heroin bound for the U.S.?

Answer. We strongly support the work of the Interdisciplinary Group of Independent Experts affiliated with the Inter-American Commission on Human Rights and commend the assistance they have provided to the Government of Mexico with respect to the investigation of the September 2014 disappearance of 43 students in Iguala, Mexico. We have encouraged Mexican authorities to incorporate the experts' findings into the ongoing official investigation.

In the reports released in September 2015 and April 2016, the experts noted the organized crime group alleged to be involved in the attack on the students and their disappearance is

connected to drug trafficking to the United States and, specifically, to a case before a federal court in Chicago. The experts hypothesized that the extreme violence against the students and the alleged “missing” fifth bus might be related to this drug trafficking—i.e., that unknown to the students who seized several buses, one of those buses could have contained drugs or drug money, which in turn led to the violent attacks of September 26, 2014. The Department of State is not in a position to evaluate the merits of that hypothesis.

WITNESSES PREPARED STATEMENTS

Prepared Statement of Daniel L. Foote, Deputy Assistant Secretary, Bureau of International Narcotics and Law Enforcement Affairs

Chairman Rubio, Senator Boxer, and distinguished Members of the Subcommittee: thank you for the opportunity to appear before you to discuss U.S. government efforts to combat the production and trafficking of heroin and the violence and instability it brings to our communities, our citizens, and the world in which we live.

The flow of illicit narcotics across our shared border with Mexico threatens citizen security in both countries. Recognizing that we have a shared responsibility to address common challenges, in 2007, the United States forged a comprehensive security partnership with Mexico. Through the Merida Initiative, we work in partnership with Mexico to build the capacity of Mexican institutions to counter organized crime, uphold the rule of law, and protect our shared border from the movement of illicit drugs, money, and goods.

The need for effective collaboration is now more important than ever. Heroin and fentanyl-laced heroin is a public health crisis in the United States, and Mexican drug trafficking organizations are the primary suppliers of heroin to the United States. We must aggressively respond to this growing threat in concert with our broader work through the Merida Initiative to counter all illicit drugs and to end the impunity with which trafficking organizations are able to operate, putting their leaders in jail, seizing their weapons, drugs, and money, and dismantling their illicit businesses.

To date through the Merida Initiative, the United States government has provided nearly \$1.5 billion worth of capacity building assistance to our Mexican partners. This includes training and equipment which complements the significant resources the Government of Mexico has dedicated to our shared security goals. Today there are more than \$700 million in bilaterally agreed upon projects with the Peña Nieto administration, which fully support the Merida Initiative’s strategic framework that underpins the basis of our security cooperation. Most of these projects fall into three priority areas: professionalizing and building the capacity of Mexican law enforcement agencies; supporting the Government of Mexico’s efforts to strengthen border management and security; and helping advance reforms across Mexico’s justice sector.

In partnership with the Department of Justice, INL is building the skills of prosecutors, investigators, and forensic experts in Mexico and preparing them for their responsibilities under the oral accusatory system, the transition to which is well underway throughout Mexico. This includes helping enhance the technical capacity of courtrooms throughout the

country to host oral trials. We are also assisting in the training of the next generation of Mexican attorneys as they learn crucial oral trial skills in Mexican law schools.

Through Merida, INL is enhancing federal, state, and municipal policing capacity throughout Mexico. These programs provide a full range of professionalization activities including: the development of enforceable police standards; basic training and academy accreditation; continuing and leadership education programs; law enforcement vetting programs; and the development of effective internal affairs units. The continued professionalization of Mexican law enforcement will result in a greater observance of and accountability for civil and human rights, increasing trust in these institutions by the people of Mexico, and making them better partners for other law enforcement organizations both within Mexico and with the United States. This is vital to any effort to stem drug trafficking and reduce the capabilities and influence of drug trafficking organizations.

Strengthening border security capacity on Mexico's borders is a priority for both our nations. Our governments have committed to further enhancing Mexico's ability to interdict illicit narcotics, arms, and money. INL has provided more than \$125 million in inspection equipment and more than 340 canine teams deployed at ports of entry, border crossings, and internal checkpoints throughout Mexico. In Mexico's northern border region, INL has provided equipment and technical assistance to improve communications between the Mexican Federal Police and U.S. Customs and Border Protection (CBP). We are working in conjunction with CBP to provide training to Mexico's Federal Police who will be deployed to the northern border region, advancing cooperation between our countries along our shared border.

Through Merida, we continue to make progress with Mexico in targeting heroin production and trafficking. We work with the U.S. Drug Enforcement Administration to provide training to augment Mexico's ability to identify, investigate, and interdict clandestine heroin labs, and better prepare Mexican authorities to dismantle them. We are improving information sharing between our governments on heroin and fentanyl, working together to better assess poppy cultivation and heroin production in Mexico, and with our interagency partners, continuing our high-level focus on exploring other avenues to enhance our bilateral cooperation when it comes to heroin.

At the last high level Security Cooperation Group held in Mexico City in October 2015, heroin was the group's highest priority. We agreed to continue working in partnership on a bilateral approach for combating the cultivation, production, and trafficking of heroin and to determine how U.S. assistance can best support Mexico's efforts in this area.

Building strong, effective justice sector institutions in Mexico capable of confronting organized crime and the violence and corruption for which it is responsible is a difficult, long-term challenge. Our work across numerous institutions and sectors must be sustained, for it is only with a concerted, committed effort that the capacity to deter the cultivation, production, and trafficking of heroin and other illicit drugs in Mexico will be strengthened. Past investments by the American people in this partnership have produced results, and with your continued support, our collaboration with Mexico on this important work will continue.

**PREPARED STATEMENT OF KEMP L. CHESTER,
ASSOCIATE DIRECTOR FOR THE NATIONAL HEROIN
COORDINATION GROUP, OFFICE OF NATIONAL DRUG POLICY**

Chairman Rubio, Ranking Member Boxer, and members of the subcommittee, thank you for inviting me to discuss the public health and public safety issues resulting from heroin use; the Government of Mexico's efforts to reduce the availability of heroin in the United States; and the U.S.-Mexico cooperation to address heroin issues in both countries.

Background

In 2014, more than 47,000 Americans, or approximately 129 people each day, died from a drug overdose. Opioids—a category of drugs that includes heroin and prescription pain medicines like oxycodone, oxymorphone, hydrocodone, and fentanyl—are having a considerable impact on public health and safety in communities across the United States. Of the overdose deaths in 2014, 61 percent (28,647) involved an opioid, 44 percent (20,808) involved prescription pain medicines, and 22 percent (10,574) involved heroin.¹ The threat posed by heroin has continued to grow dramatically over the past several years. Since 2007, deaths involving heroin have risen 340 percent, from 2,402 in 2007 to 10,574 in 2014.²

There are several principal factors contributing to the current nationwide heroin crisis: the increased availability of heroin in the U.S. market,³ the availability of purer forms of heroin that allow for non-intravenous use,⁴ its relatively low price,⁵ and a relatively small percentage of non-medical users of opioid prescription drugs transitioning to heroin.⁶ The purity of retail-level heroin has increased since the 1990s while prices have remained low.⁷ Further increases in purity since 2010 have enabled heroin use by a variety of means including snorting or smoking which broadens the drug's appeal to a large population that is disinclined to inject the drug intravenously. Heroin's relatively low price makes it a viable alternative to many prescription opioids which command higher prices on the street.⁸ Heroin use has spread into suburban and rural communities and is growing among most socioeconomic classes, age groups, and races.⁹

¹ An opioid-related death may involve more than one type of opioid.

⁹ Cicero, T., Ellis, MS, Surratt, HL, Kurtz, SP. (2014). The changing face of heroin in the United States: A retrospective analysis of the past 50 years. JAMA Psychiatry, 71(1): 821-826.

The Administration recognizes that the heroin threat is a global issue; however, Mexico is currently the primary supplier of heroin to the United States, with Mexican drug traffickers cultivating opium poppy and producing heroin in Mexico, and smuggling the finished product into the United States.¹⁰ Opium poppy cultivation in Mexico has increased substantially in recent years, rising from 17,000 hectares in 2014, with an estimated potential pure heroin production of 42 metric tons, to 28,000 hectares in 2015 with a potential production of 70 metric tons of pure heroin.¹¹

The reemergence of illicit fentanyl, a powerful Schedule II synthetic opioid more potent than morphine or heroin, exacerbates the heroin crisis.¹² Illicit fentanyl is sometimes mixed with powder heroin to increase its effects or with diluents and sold as “synthetic heroin,” with or without the buyers’ knowledge.¹³ Increasingly, illicit fentanyl is pressed into pill form and sold as counterfeit prescription opioid pills. Illicit fentanyl comes from several sources. The majority of the illicit fentanyl in the U.S. market is smuggled into the country after being clandestinely produced in Mexico or China.¹⁴

Illicit fentanyl is extremely dangerous and deadly. In 2014, there were more than 5,544 drug overdose deaths involving synthetic narcotics other than methadone, a category that includes fentanyl. This number has more than doubled from two years earlier (2,628 in 2012).¹⁵ Moreover, overdose deaths involving opioids like illicit fentanyl are likely undercounted. Of deaths where drug overdose is cited as the underlying cause of death, approximately one-fifth of the death certificates do not list the specific drug(s) involved in the fatal overdose.¹⁶

There are several reasons why it is important that we address concerns regarding heroin and illicit fentanyl in a single problem set. First, traffickers who add illicit fentanyl as an adulterant to boost the effect of their heroin, or mix it with diluents to sell as synthetic heroin, likely utilize the same supply chains and distribution mechanisms for both drugs. Moreover, both heroin and fentanyl belong to the same class of opioid drugs that have similar effects making their illicit user populations one and the same. Second, both heroin and clandestinely-produced fentanyl can be manufactured by the same drug trafficking organizations that can bring both drugs into the country using the same trafficking routes. And finally, addressing both illicit drugs together allows us to address the heroin crisis while avoiding unintended uptick in illicit fentanyl use. If we move too quickly in reducing the availability of heroin

without simultaneously addressing illicit fentanyl availability, it could increase the price of heroin, and risk driving more people to use illicit fentanyl—thereby creating the prospect of an additional and potentially more deadly opioid drug threat.^{17,18}

The dramatic increase in the availability and use of heroin and illicit fentanyl is a national security, law enforcement, and public health issue, and it has become the highest priority illicit drug threat to the Nation.¹⁹ Addressing this complex problem demands significant effort, creativity, and interagency collaboration.

The Federal Response

The National Heroin Coordination Group

In November of 2015, the National Security Council (NSC) Transborder Security and Western Hemisphere Directorates Interagency Policy Committee (IPC) on Mexico Security Priorities directed the formation of the National Heroin Coordination Group (NHCG) within the Office of National Drug Control Policy (ONDCP). The NHCG is the hub of a network of interagency partners who leverage their home agency authorities and resources to synchronize interagency activities against the heroin and illicit fentanyl supply chains to the United States. I serve as the Director of the NHCG, which ensures that Federal counterdrug efforts focused on the heroin problem complement the NSC's ongoing work related to Mexico security priorities, and that the NHCG connects the actions taken on the front end of the supply chain with the effects on the domestic market and user population.

Bi-Lateral Engagement

U.S.-Mexico engagement regarding heroin has been robust. In October 2015, ONDCP Director Michael Botticelli participated in a U.S.- Mexico Security Cooperation Group dialogue that included heroin as the first security cooperation agenda topic. The importance of increased poppy eradication efforts by the Government of Mexico, as well as drug interdiction, clandestine laboratory destruction, and disruption of precursor chemical trafficking were all highlighted as crucial issues to be addressed.

Director Botticelli and I traveled to Mexico in early March 2016 with Ambassador William Brownfield, Assistant Secretary of State for International Narcotics and Law Enforcement Affairs (INL), to engage on heroin and illicit fentanyl issues specifically and to impress upon our Mexican partners the urgency with which the United States is addressing the heroin problem. We met with Mexican Attorney General Gómez and senior members of her staff, as well as with senior officers from the Mexican Army, the Mexican Navy, and the Secretariat of the Government. Attorney General Gómez announced her role as the synchronizer of Mexico's efforts to disrupt the production of heroin and illicit fentanyl including poppy eradication and the identification and neutralization of production laboratories.

¹⁹ The White House, Strategy to Combat Transnational Organized Crime, 25 July 2011.

Importantly, we agreed to conduct joint planning and to develop a simple and focused national strategy to direct and concentrate Mexico's efforts against heroin and illicit fentanyl. We expect this plan to delineate responsibilities, identify gaps, and help synchronize heroin and illicit fentanyl efforts across the Mexican government. This plan will be beneficial for both countries and we look forward to collaborating on its development. The country team at the U.S. Embassy in Mexico City has led efforts to foster partnerships within the Government of Mexico, and increased information sharing continues to enhance this relationship. The United States continues to work with the Government of Mexico on important efforts under the Merida Initiative, a joint effort to fight transnational criminal organizations and reduce associated violence. Building upon the Mexican Government's own investment in equipment and border security infrastructure, the Merida Initiative will continue to strengthen border security that facilitates the flow of legitimate commerce and travel, while reducing the movement of illicit narcotics, currency, weapons, explosives, black market goods, and undocumented migrants.

U.S. Federal law enforcement agencies are aggressively addressing the heroin and illicit fentanyl issue both here and abroad. The Drug Enforcement Administration and other agencies have co-located Special Agents with international partners in Mexico and throughout Latin America to assist in criminal investigations targeting drug trafficking organizations, and to help their international counterparts develop their capacity to conduct the full range of narcotics interdiction activities within their countries to target both heroin and illicit fentanyl. Our Federal law enforcement agencies, in conjunction with the Department of State, are working with the countries who supply illicit fentanyl and the precursor chemicals used in its manufacture to stem the flow of these dangerous chemicals to the Western Hemisphere.

Interagency Partnerships

Our ability to bring together, contextualize, and synchronize the strategies and partnerships currently taking place at the Federal, state, local, and tribal levels to reduce the availability of heroin in the United States is critical to our overall efforts. The urgent need to sustain progress toward addressing the heroin crisis, combined with the expanding and dynamic nature of the problem itself, requires increased collaboration among Federal agencies, and with our partners working at the state, local and tribal level where the crisis is felt most deeply and where there is an enormous amount of energy and innovation. This cooperation will allow for greater situational awareness to provide more comprehensive understanding of expected changes in the domestic environment related to interagency heroin/illicit fentanyl supply reduction efforts.

The ONDCP funded High Intensity Drug Trafficking Areas (HIDTA) Program is a locally-based program that responds to the drug trafficking issues facing specific areas of the country. Law enforcement agencies at all levels of government share information and implement coordinated enforcement activities; enhance intelligence sharing among Federal, state, local, and tribal law enforcement agencies; provide reliable intelligence to law enforcement agencies to develop effective enforcement strategies and operations; and support coordinated law enforcement strategies to maximize available resources and reduce the supply of illegal drugs in designated areas. In August 2015, ONDCP committed \$2.5 million in HIDTA funds to develop a strategy to respond to the heroin crisis in the United States. This unprecedented project combines prevention, education, intelligence, and enforcement

resources to address the heroin threat across 17 states and the District of Columbia. The effort is carried out through a unique partnership of seven regional HIDTAs—Appalachia, Michigan, New England, New York/New Jersey, Ohio, Philadelphia/Camden, and Washington/Baltimore. The HIDTA heroin response strategy will foster a collaborative network of public health-public safety partnerships, sharing best practices, innovative pilots, and identifying new opportunities to leverage resources.

Along our Southwest border, U.S. Customs and Border Protection (CBP) continues to detect and interdict illicit narcotics entering the United States. CBP reports seizing 1,121,411 kilograms of illegal drugs in 2015. Of that amount, CBP seized 2,745 kilograms of heroin, 25 percent more than CBP seized in 2014.

The Department of Justice's Organized Crime Drug Enforcement Task Forces (OCDETF) partnered with the Federal Bureau of Investigation, Homeland Security Investigations, and the Drug Enforcement Administration target, disrupt, and dismantle international drug trafficking organizations that manufacture, transport, and distribute heroin and illicit fentanyl destined for and distributed across the United States. In addition, OCDETF's National Heroin Initiative, launched in December 2014, seeks to coordinate innovative regional approaches that improve information sharing and data collection to support multi-agency, multi-jurisdictional enforcement actions.

Challenges

While we have worked tirelessly to address the heroin crisis and have laid a firm foundation for future efforts, much remains to be done. We have gaps in our capability to detect illicit fentanyl at our borders and in our air freight package locations, and our Mexican partners could certainly do more to strategically dismantle criminal organizations and conduct opium poppy eradication and clandestine laboratory identification and neutralization.

We are working to close information gaps. Although it is abundantly clear that the number of overdose deaths involving illicit fentanyl nationwide has increased dramatically, it is likely that the overdose numbers underreport the actual number of deaths due to heroin and illicit fentanyl. The ability to detect illicit fentanyl in overdose victims, and the standard inclusion of illicit fentanyl in overdose death toxicology screening, varies widely among localities. This likely results in the undercounting of heroin and illicit fentanyl-related deaths and actual numbers of heroin-related overdoses are probably much higher. In localities where detailed toxicology screening is performed, information suggests higher numbers of illicit fentanyl-related overdose.

We look forward to working with our Federal and state government partners, as well as our international counterparts, to address these problem areas.

Conclusion

We cannot forget that the epidemic of opioid use and overdose deaths is fundamentally a public health problem that is exploited by criminal organizations, and addressing it adequately requires substance use prevention and treatment strategies and recovery support

services. Law enforcement officials are increasingly becoming public health partners, linking individuals with opioid use disorder to treatment.

For this reason, in the FY 2017 budget President Obama proposed \$1 billion in new mandatory funding over two years to expand the availability of opioid use disorder services, target areas of highest need, and allow states to implement evidence-based strategies that best meet local needs, such as medication-assisted treatment and expansion of the availability of substance abuse treatment providers (through enhanced loan repayment for healthcare providers that offer medication-assisted treatment). Such efforts will help individuals seek treatment, successfully complete treatment, and sustain recovery.

ONDCP will continue to work with our Federal government departments and agencies, partners at the state, local and tribal levels, and international counterparts to reduce heroin and illicit fentanyl production and trafficking and to combat the profound effect these dangerous drugs are having in our communities.

Thank you for affording me the opportunity to testify today and for your commitment to this important issue.

PREPARED STATEMENT OF TERESA JACOBS, MAYOR OF ORANGE COUNTY, FLORIDA

Chairman Rubio, Ranking Member Boxer, members of the committee, thank you for calling this important hearing, and for allowing me to share a local perspective on the terrible threat that heroin poses for cities and counties throughout our country.

First a bit about Orange County: We're home to the City of Orlando and 12 other municipalities, with a population of 1.2 million people, a strong economy and an exceptional quality of life. In 2015, we shattered national tourism records, hosting more than 66 million visitors.

No doubt you know us as the vacation capital of the world, but tragically, like too many other states and communities, Orange County has seen an alarming increase in the number of heroin overdoses and related deaths. Last year, we lost 85 lives to heroin—a staggering 600% increase since 2011. Already this year we've had more than 90 heroin overdoses in the county, with about one-in-ten resulting in death.

Florida's fight against this current wave of opioid addiction began about five years ago, in the midst of our battle against the pill mills.

You may remember the shocking statistics from 2010, when it was discovered that Florida practitioners purchased more than 41 million oxycodone pills in the first six months of that year—more than the other 49 states of the union combined.

Like countless cities, towns and counties across the U.S., we worked to outlaw unauthorized pain clinics and provide resources for breaking opioid addiction.

In Florida, the pill mill 'legacy' has impacted us beyond measure. I can't prove it, but I think it's very likely that cartels took notice of what they perceived to be a ripe "marketplace." Today, predatory drug dealers are targeting us with heroin, as well as cheap and deadly strains of fentanyl. Unfortunately, it's nearly impossible to accurately assess the threat in Florida, since no statewide databases exist. Instead, numbers are captured by individual agencies and municipalities—there is simply no mechanism for synergy or sharing.

What we do know? We know that last year, approximately 2,000 heroin users moved through our Orange County jail. Many of those were arrested not for heroin possession, but for other offenses related to heroin addiction.

We know that in 2015, we housed 100 expectant mothers tragically addicted to opiates or heroin, as our Jail has become the treatment center of last resort for so many people.

For the good of our citizens and our community, we are fighting back.

Last summer I convened the Orange County Heroin Task Force, and asked our sheriff to Co-Chair the effort. Our joint work is having a positive impact, including passage in the 2016 Florida Legislature of a measure allowing Naloxone sales without an individual prescription.

We know there is no single solution, but there are some universally effective approaches:

- Enforcement is critical. In a world of increasingly sophisticated technology, our local efforts—no matter how highly leveraged and coordinated—are simply no match against organized traffickers.
- Equally important, and in keeping with what we learned with pill mills, we must be tireless in educating people that addiction is an illness. An illness that requires treatment and support not only for the addict, but also for the families who are ravaged by addiction.

In closing, I respectfully ask for your help:

- *Help to stop the influx of drugs* across the border. We've got our hands full at the local level, and are simply not equipped to fight the cartels. This is where we really need your help—to stop these deadly drugs before they cross our borders.
- *Help to treat more addicts.* With a regional population of 2.5 million, we have one Addictions Receiving Facility with 26 detox beds serving four counties for the uninsured.
- *Help to raise awareness* so more people will choose not to try this deadly drug in the first place.

To end this crisis and save lives, we all need to be engaged. Thank you for your attention to this critical issue and thank you for your leadership and your service.

PREPARED STATEMENT OF STEVEN DUDLEY, CO-DIRECTOR, INSIGHT CRIME

Chairman Rubio, Ranking Member Boxer, and members of the subcommittee: I am grateful for the opportunity to appear before you on behalf of InSight Crime and the Center for Latin American and Latino Studies at American University to discuss the criminal dynamics connected to the illegal opiate market, specifically the heroin market in the United States related to poppy production in Mexico.

Mexico's Increased Market Share

U.S. consumption of heroin has increased significantly in the last few years. The reasons for this are complex but have to do with the increase of prescription drugs in the United States, a rise in prices of these prescription drugs and their black market counterparts, and the subsequent safeguards on this prescription medicine market, specifically OxyContin.

The U.S. portion of the world heroin market is small by comparison in terms of users, but outsized in terms of potential earnings. The Rand Corporation estimated in 2014, that U.S. consumers spend as much as \$27 billion on heroin each year, an increase from \$20 billion per year in 2000.²⁰ Only the marijuana market is worth more in the U.S.²¹

Mexican, Guatemalan and Colombian criminal organizations have reacted to these changes by producing more heroin. Only a small percentage of the world's opium poppy is cultivated in this hemisphere, but after it is processed into heroin, almost all of it is sold in the United States where the number of consumers for the drug has more than doubled since the early 2000s.

Mexico accounts for the bulk of poppy production in the region. According to estimates by the Drug Enforcement Administration (DEA), the production of poppy, the raw ingredient for the production of heroin, increased from 10,500 hectares in 2012 to 17,000 hectares in 2014, giving the groups the potential to produce 42 metric tons, up from 26 metric tons in 2012.²² By comparison, the DEA says Colombia produces only two metric tons per year.²³

Seizure data of heroin along the southwest border also indicate that Mexican criminal groups are moving increasing amounts of heroin into the U.S. market. Mexican criminal organizations are also the key transporters of Colombian heroin to the United States, and they manage and purchase the heroin produced in Guatemala or buy the opium gum wholesale to process it into heroin themselves in Mexico.

Inside the U.S., the trend appears to be the same. The DEA says that Mexican groups are seeking an increasing amount of the market share in the distribution business itself, displacing other wholesalers. In sum, the picture is one of an increasingly lucrative, vertically integrated market, with large Mexican criminal organizations managing the product from the point of production to the point of sale and seeking a greater market share of these sales.

The Reality of the Heroin Supply Chain

The reality of the supply chain is much more complex. While it helps us to use well-worn monikers when talking about these organizations, the truth is that they are not nearly as strong or monolithic as they once were. Names such as the Tijuana Cartel, the Juárez Cartel, the Zetas, or La Familia Michoacana may still evoke fear and sometimes awe, but they are not organizations as much as brand names. In many cases, the individual parts of the organization have as much contact with the bosses as a local Coca-Cola bottling plant manager might have with corporate headquarters.

²⁰ Beau Kilmer, et al., "How Big is the U.S. Market for Illegal Drugs," Rand Corporation (2014).

²¹ Ibid.

²² Drug Enforcement Administration (DEA), "National Drug Threat Assessment 2015," p. 34

²³ . The United Nations' most recent estimate for global heroin production is 526 tons. See: UNODC, "World Drug Report 2015," p. 41. Av.

Even the vaunted Sinaloa Cartel is more horizontally than vertically integrated. Take the recent case of the Flores brothers in Chicago. Before they were arrested, Pedro and Margarito Flores were said to be Sinaloa Cartel distributors in Chicago, one of the areas of greatest interest to this subcommittee. And they were. But as federal intercepts of their conversations with cartel leaders show, the two brothers negotiated independently with each of the top two members of the Sinaloa criminal organization, obtaining different prices with different leaders and managing shipments separately.²⁴ Even after a war started between the Sinaloa Cartel and the Beltrán Leyva Organization, the Flores brothers continued to purchase drugs from portions of the Beltrán Leyva Organization and the Sinaloa Cartel.

The Flores case cuts at two different myths about the Sinaloa Cartel: 1) that this is one single organization; 2) that it is tightly controlled by a single leader or a single group of leaders. The point is that as shipments get further and further from Mexico's wholesale points, the loyalties become more disperse, and in some cases completely disappear. This is especially true in the U.S. market where violence is not a viable long-term option to ensure loyalty, win market share or become a monopoly.

The effectiveness of U.S. law enforcement has made violence terrible for business and made the distribution chain a more democratic, capitalist affair. This is evident in other ways as well. While the amount of seizures indicates that there is more heroin available in the United States, it is still moved in very small quantities. The median seizure for the Los Angeles Field Division of the DEA in 2014, for example, was a kilogram.²⁵ In Denver, a 10 to 12 pound shipment is considered large.²⁶

The amount of profits reaped by these Mexican criminal organizations also raises questions about how much control they exert in the United States. The Rand Corporation estimated in 2010 that Mexican criminal groups earn in the range of \$400 million per year from their heroin exports and possibly another \$700 million for transporting Colombian heroin to the U.S. market.²⁷ While this has undoubtedly increased, there is still the question of where the rest of the over \$20 billion spent on heroin in the U.S. annually goes.

The case of the Laredo brothers, recently indicted in the Eastern District of Pennsylvania, is indicative of these trends. The Laredo brothers are charged with moving one ton of heroin over a six-year period. This is about 14 kilos per month. The organization was so subtle and, as one Mexican analyst put it, "mom-and-pop," the Mexican authorities did not even know it existed.²⁸

This brings us to Mexico. First, it is important to note that, unlike the cocaine market, Mexico is not dependent on other countries for its product. It is home grown. Second, the horizontal nature of the distribution chain makes it a difficult law enforcement problem in that country as well. As noted, the once monolithic criminal organizations are shells of what they once were. This is in part due to in-fighting of the type mentioned earlier but also Mexican law enforcement efforts. Many of the fragmented pieces have formed their own criminal operations and brand names.

²⁴ Michelle Garcia, "Court Docs Raise Questions about Mexico Sinaloa Cartel Narrative," 12 November 2013.

²⁵ DEA, *op. cit.*, p. 37.

²⁶ *Ibid.*

²⁷ Kilmer, et al., "Reducing Drug Trafficking Revenues and Violence in Mexico: Would Legalizing Marijuana in California Help?," Rand Corporation (2010), p. 30.

²⁸ Alejandro Hope, "The Laredo DTO and what it says about the heroin trade," 19 April 2016.

The most well-known is arguably the Guerreros Unidos, the criminal group held responsible for the disappearance of the 43 students in Mexico in 2014. The Guerreros Unidos used to be under the umbrella of the Beltrán Leyva Organization. When the Beltrán Leyva Organization fell to pieces during their war with the Sinaloa Cartel, the Guerreros Unidos became independent, as did several other criminal groups in the embattled state of Guerrero, which is one of the centers of opium cultivation, heroin production, wholesale and transport. Indeed, the mystery of what happened to those students, may hinge on whether the Guerreros Unidos were using commercial buses to move heroin to Chicago.²⁹

The upshot is that the chain of production in Mexico is broken into numerous pieces, including small and large producers of opium poppy plants, the opium gum producers, the processors, the wholesale purchasers, and the transporters. Production, transport and distribution may all be different organizations. The Laredo brothers, for example, were purchasing opium gum from an independent broker then processing it themselves and distributing it in those small quantities in the U.S. for years without running into trouble with the large, supposedly all-controlling Sinaloa Cartel.

To be sure, violence is still a viable option in Mexico, so the pendulum may swing back towards more monolithic criminal organizations. But for the moment, the reality is that there are literally dozens of small criminal organizations involved in this trade from the point of production to the point of sale.

Impact on Law Enforcement Efforts

In sum, while the level of control that the Mexican production and transport groups exert over the supply chain is clear, we are not talking about one or two criminal groups, but dozens of interlocking organizations whose alliances are constantly shifting. The heroin supply chain appears to be a largely horizontal, diversified operation with multiple actors, and one that is obedient to market forces rather than one or two single vertically integrated distributors.

The result is that law enforcement efforts are largely muted. Whether you debilitate the Sinaloa Cartel or the Laredo brothers, you are hindering a small part of the overall production and distribution chain. Even if you did slow the heroin from Mexico, you would face an insurmountable task: stopping the flow from other countries, which would undoubtedly fill the void and account for the bulk of world-wide production. Canada already gets up to 90 percent of its heroin from Afghanistan.³⁰

And the United States once got all of its heroin from the Asian markets that supply the rest of the world.

Thank you for your time and attention. I look forward to your questions.

³⁰ UNODC, *op. cit.*, p. 46.

STATEMENT FOR THE RECORD SUBMITTED BY JACK RILEY, ACTING DEPUTY ADMINISTRATOR, DRUG ENFORCEMENT ADMINISTRATION

Introduction

Chairman Rubio, Ranking Member Boxer, and members of the subcommittee, on behalf of the approximately 9,000 employees of the Drug Enforcement Administration (DEA), thank you for the opportunity to discuss the issue of Cartels, the U.S. heroin epidemic, and DEA's response to combating the drug violence and public health crisis.

Today, Mexican Transnational Criminal Organizations (TCOs) remain the greatest criminal drug threat to the United States; no other group can challenge them in the near term. These Mexican poly-drug organizations traffic heroin, illicit fentanyl, methamphetamine, cocaine, and marijuana throughout the United States, using established transportation routes and distribution networks. They control drug trafficking across the Southwest border (SWB) and are moving to expand their share of U.S. illicit drug markets, particularly heroin markets.

National-level gangs and neighborhood gangs continue to form and expand relationships with Mexican TCOs. Many gangs rely on Mexican TCOs as their primary drug supply source, and Mexican TCOs depend on street-level gangs, many of which already have a customer base, for drug distribution. Additionally, gangs profit through drug transportation activities, enforcement of drug payments, and by securing drug transportation corridors from use by rival gangs.

Mexican TCOs exploit a user population struggling with the disease of addiction. Drug overdoses are the leading cause of injury-related death in the United States, eclipsing deaths from motor vehicle crashes or firearms.³¹ There were over 47,000 overdose deaths in 2014, or approximately 129 per day, over half (61 percent) of which involved either a prescription opioid or heroin.³² These are our family members, friends, neighbors, and colleagues.

The DEA's focus is targeting the most significant, sophisticated, and violent trafficking organizations that profit from exploiting persons with substance use disorders. DEA's strategic priorities include targeting Mexican Consolidated Priority Organization Targets (CPOTs) and Priority Target Organizations (PTOs), which are the most significant international and domestic drug trafficking and money laundering organizations.

Current Assessment of the Threat

Based on active law enforcement cases, the following Mexican TCOs are operating in the United States: the Sinaloa Cartel, Beltrán-Leyva Organization (BLO), New Generation Jalisco Cartel (Cartel de Jalisco Nueva Generación or CJNG), Los Cuinis, Gulf Cartel (Cartel del Golfo or CDG), Juarez Cartel Michoacán Family (La Familia Michoacána or LFM), Knights Templar (Los Caballeros Templarios or LCT), and Los Zetas. While all of these Mexican TCOs transport wholesale quantities of illicit drugs into the United States, the

³¹ Centers for Disease Control and Prevention, Web-based Injury Statistics Query and Reporting System (WISQARS) [online], (2014).

³² Rose A. Rudd, Noah Aleshire, Jon E. Zibbell, R. Matthew Gladden. Increases in Drug and Opioid Overdose Deaths—United States, 2000–2014 *Morbidity and Mortality Weekly Report*, 2016;64:1378–1382.

Sinaloa Cartel remains the most active supplier. The Sinaloa Cartel leverages its expansive resources and organizational structure in Mexico to facilitate the smuggling and transportation of drugs throughout the United States.

Mexican TCO operations in the United States typically take the form of a supply chain system that relies on compartmentalized operators who are only aware of their own specific function, and remain largely unaware of other operational aspects. In most instances, transporters for the drug shipments are independent third parties who work for more than one Mexican TCO. Since operators in the supply chain are insulated from one another, if a transporter is arrested the transporter is easily replaced and unable to reveal the rest of the network to law enforcement.

Mexican TCOs in the United States utilize a network of extended family and friends to conduct their operations. Families affiliated with various Mexican TCOs in Mexico vouch for U.S.-based relatives or friends that are deemed trustworthy to run various aspects of the drug trafficking operations in the United States. Actual members of Mexican TCOs are usually sent to important U.S. hub cities to manage stash houses containing drug shipments and bulk cash drug proceeds. While operating in the United States, Mexican TCOs actively seek to maintain low profiles and avoid violent confrontations between rival TCOs or U.S. law enforcement.

Mexican TCOs transport illicit drugs over the SWB through ports of entry using passenger vehicles or tractor trailers. Illicit drugs are typically secreted in hidden compartments when transported in passenger vehicles or comingled with legitimate goods when transported in tractor trailers. Once across the SWB, Mexican TCOs will initially utilize stash houses in a number of hub cities to include Dallas, Houston, Los Angeles, Atlanta, and Phoenix. The illicit products will then be transported via these same conveyances to distribution groups in the Midwest and on the East Coast. Mexican TCOs also smuggle illicit drugs across the SWB using other methods including tunnels, maritime conveyances, and aircraft.

Heroin Availability to the U.S. Market

There are four major heroin-producing areas in the world, but heroin bound for the U.S. market originates predominantly from Mexico and, to a lesser extent, Colombia. The heroin market in the United States has been historically divided along the Mississippi River, with western markets using Mexican black tar and brown powder heroin, and eastern markets using white powder, which over the last two decades has been sourced primarily from Colombia. The largest, most lucrative heroin markets in the United States are the white powder markets in major East Coast cities: New York City and the surrounding metropolitan areas, Philadelphia, Boston and its surrounding cities, Washington, D.C., Baltimore, as well as Chicago. Given the growing number of individuals with an opioid use disorder in the United States, Mexican TCOs have seized upon a business opportunity to increase their profits. Mexican TCOs are now competing for the East Coast and Mid-Atlantic markets by introducing Mexican brown/black tar heroin, as well as by developing new techniques to produce highly refined white powder heroin.

Poppy cultivation in Mexico increased 160 percent between 2013 and 2015, resulting in an estimated 70 metric tons of potential heroin. Cultivation in Mexico is located primarily in the state of Guerrero and the Mexican ‘Golden Triangle’ which includes the states of Chihuahua, Sinaloa, and Durango. The increased cultivation and trafficking from Mexico to the United States impacts both of our nations by supporting the escalation of heroin use in the United States, as well as the instability and violence associated with drug trafficking in Mexico.

The majority of Mexican and Colombian heroin bound for the United States is smuggled into the United States via the SWB, and heroin seizures at the border have more than doubled, from 1,016 kilograms in 2010 to 2,524 kilograms in 2015.³³ During this time, the average seizure at the Border also increased from 2.0 kilograms to 3.5 kilograms. Most heroin smuggled across the border is transported in privately-owned vehicles, usually through California, as well as through south Texas. In 2014, more than half of U.S. Customs and Border Protection (CBP) heroin seizures at the SWB were in the southern California corridors of San Diego and El Centro. The distribution cells, and the Mexican and South American traffickers who supply them, are the main sources of heroin in the United States today. In Mexico, the threat of these organizations is magnified by the high level of violence associated with their attempts to control and expand drug distribution operations.

DEA has become increasingly alarmed over the addition of fentanyl into heroin sold on the streets as well as the use of fentanyl analogues such as acetyl fentanyl. The more potent opioids like fentanyl³⁴ present a serious risk of overdose death for a user. In addition, this drug can be absorbed by the skin or inhaled, which makes it particularly dangerous for law enforcement, public safety, or health care personnel who encounter the substance during the course of their daily operations. On March 18, 2015, DEA issued a nationwide alert to all U.S. law enforcement officials about the dangers of illicit fentanyl and fentanyl analogues and related compounds. In addition, due to a recent spike in overdose deaths related to the use of acetyl fentanyl, on July 17, 2015, DEA used its emergency scheduling authority to place acetyl fentanyl in Schedule I of the CSA.

DEA Response to the Heroin Threat

DEA’S 360 Strategy

DEA is rolling out the 360 Strategy to address the opioid, heroin, and violent crime crisis. The strategy leverages existing federal, state, and local partnerships to address the problem on three different fronts: law enforcement, diversion control, and community relations. The strategy is founded upon our continued enforcement activities directed at the violent street gangs responsible for feeding the heroin and prescription drug abuse epidemic in our communities.

While law enforcement plays a central role in the 360 Strategy, enforcement actions alone are not enough to make lasting changes in our communities. The 360 Strategy, therefore, also focuses on preventing diversion by providing education and training within the

³³ Drug Enforcement Administration, *Unclassified Summary, 2015 National Drug Threat Assessment*, Pg. 35.

³⁴ Centers for Disease Control, *Emergency Response Safety and Health Database, FENTANYL: Incapacitating Agent*, accessed March 19, 2015; U.S. Department of Justice, *Drug Enforcement Administration, Office of Diversion Control, Drug & Chemical Evaluation Section, Fentanyl*, March 2015.

pharmaceutical community and to pursue those practitioners who are operating outside of the law. The final component of the strategy is a community effort designed to maximize all available resources to help communities turn around the recurring problems that have historically allowed the drug and violent crime problems to resurface after enforcement operations.

Additional Resources in Fiscal Year 2017

DEA plays an important part in the U.S. government's drug control strategy that includes enforcement, treatment, and prevention. While there are complex issues affecting spikes in heroin use and overdoses, including prescription drug abuse, the same significant poly-drug trafficking organizations responsible for other illicit drug threats are also responsible for the vast majority of the heroin supply. Additionally, drug trafficking has a proven linkage to gangs and other violent criminal organizations. The FY 2017 President's Budget request provides \$12.5 million and 42 positions, including 32 special agents, to create new enforcement groups in DEA domestic field divisions.

Heroin Task Force

As directed by Congress, the Department of Justice joined with the Office of National Drug Control Policy (ONDCP) to develop strategies to confront the heroin problem and curtail the escalating overdose epidemic and death rates. DEA and more than 28 Federal agencies and their components participated in this initiative. The task force provided its Report to Congress on December 31, 2015.

International Enforcement: Sensitive Investigative Units

DEA's Sensitive Investigative Units (SIU) program, nine of which are in the Western Hemisphere, helps build effective and vetted host nation units capable of conducting complex investigations targeting major TCOs. DEA, with funding support from the Department of State, currently mentors and supports 13 SIUs, which are staffed by over 900 foreign counterparts. The success of this program has enhanced DEA's ability to fight drug trafficking on a global scale.

International Enforcement: Bilateral Investigations Units

Bilateral Investigations Units (BIUs) are one of DEA's most important tools for targeting, disrupting, and dismantling significant TCOs. The BIUs have used extraterritorial authorities to infiltrate, indict, arrest, and convict previously "untouchable" TCO leaders involved in drug trafficking.

Special Operations Division

Established in 1994, the Special Operations Division (SOD) is a DEA-led multi-agency operations coordination center with participation from Federal law enforcement agencies, the Department of Defense, the Intelligence Community, and international law enforcement partners. SOD's mission is to establish strategies and operations to dismantle national and international trafficking organizations by attacking their command and control communications. Special emphasis is placed on those major drug trafficking and narco-

terrorism organizations that operate across jurisdictional boundaries on a regional, national, and international level.

El Paso Intelligence Center

The El Paso Intelligence Center (EPIC) is a national intelligence center focused on supporting law enforcement efforts in the Western Hemisphere with a significant emphasis on the SWB. Through its 24-hour watch function, EPIC provides law enforcement officers, investigators, and analysts immediate access to participating agencies' databases. This function is critical in the dissemination of relevant information in support of tactical and investigative agencies, deconfliction, and officer safety. EPIC also provides significant tactical, operational, and strategic intelligence support to state and local law enforcement agencies, especially in the areas of clandestine laboratory investigations and highway interdiction.

Cooperation with Mexico

The DEA's presence in Mexico represents our largest international footprint. The ability to have DEA Special Agents assigned to 11 different offices throughout Mexico is a reflection of the level of cooperation that we continue to enjoy with our Mexican counterparts. DEA supports bi-lateral investigations with the Government of Mexico by providing information and intelligence to develop investigations that target leaders of TCOs throughout Mexico.

We view our working relationship with the Mexican Authorities as strong, and getting stronger. In 2014, Mexican law enforcement officials arrested cartel leaders Hector Beltrán-Leyva, Servando Gomez-Martinez, and Omar Trevino Morales. These actions represent significant successes for both the United States and Mexico in our shared struggle against TCOs. The arrests struck at the heart of the leadership structure of the Knights Templar Cartel, the Beltrán-Leyva Organization, and the Los Zetas Cartel; and highlight the continuing cooperation between Mexican and U.S. law enforcement. The United States and Mexico have established a strong and successful security partnership in the last decade and, to that end, the U.S. government stands ready to work with our Mexican partners to provide any assistance, as requested, to build upon these successes.

Conclusion

Mexican TCOs remain the greatest criminal drug threat to the United States. These Mexican poly-drug organizations traffic heroin, methamphetamine, cocaine, and marijuana throughout the United States, using established transportation routes and distribution networks. They control drug trafficking across the SWB and are moving to expand their share of U.S. illicit drug markets. Their influence up and down the supply chain, their ability to enter into new markets, and associations with domestic gangs are of particular concern for the DEA. DEA will continue to address this threat domestically and abroad by attacking the crime and violence perpetrated by the Mexican-based TCOs which inflict tremendous harm to our communities.

Chapter 532

**THE IMPLEMENTATION OF THE COMMON
ASSESSMENT FRAMEWORK IN PUBLIC HEALTHCARE
ORGANIZATIONS: IMPROVING PATIENT SAFETY
THROUGH IMPROVEMENT OF
ORGANIZATIONAL PERFORMANCE**

ABSTRACT

The Common Assessment Framework (CAF) constitutes a holistic analysis of the performance of one organization, approaching it from different perspectives simultaneously. According to this, the excellent results for the organizational performance, citizens/customers and society rely on leadership, planning/design, human resources, partnerships, resources, as well as administrative processes. CAF is based on 8 basic principles, the so called “Excellence Principles”, namely Results orientation, Focus on citizen/customer, Leadership and Consistency of aim, Management through processes and facts, Development and participation of human resources, Continuous learning, Innovation and improvement, Development of partnerships and Corporate social responsibility. These principles have been incorporated in the CAF structure through 9 criteria, which are further analyzed in 28 subcriteria. Each of the principles has 4 maturity levels, which define over time the course of one organization towards excellence. The CAF 9 criteria represent the main aspects that need to be taken into consideration during the analysis of any organization. These are categorized in 5 criteria- enablers, which cover what the organization does (Leadership, Strategy & Planning, Human Resources,

* Corresponding Author’s Email: stellkor@gmail.com.

Partnerships & Resources and Processes) and 4 criteria- results, which cover what the organization achieves (Citizens/Customers oriented results, Human Resources oriented results, Society oriented results and Key performance results). By conducting a self-assessment Public Organizations may define in their function their strengths, as well as areas for improvement. The self-assessment process is guided by a specific rating system. The CAF implementation is a continuous process, as the conclusions from one assessment should lead to a plan with improvement actions, which, after their implementation, should be re-assessed using the CAF, so to achieve continuous administrative improvement. As a conclusion, the CAF is a Total Quality Management (TQM) tool that Public Organizations can use for free for their self-assessment, aiming at improving their administrative capacity and services, without having to ask for support from external sources.

Keywords: self-assessment of hospital, common assessment framework, quality in healthcare services

INTRODUCTION

The CAF belongs to the TQM tools and in Europe it is used for free as of year 2000 to assist Public Organizations in using TQM techniques in a simple way so that they can improve their administrative capacity and the services provided to citizens and other enterprises.

The CAF constitutes a holistic analysis of one organization, approaching it from different perspectives simultaneously and assessing the results achieved, either by its entirety or by its different divisions, in terms of organizational performance, citizens'/customers' satisfaction and society's satisfaction (EIPA, 2019). By being common for Organizations of the Public Sector, it ensures comparability of results among similar services.

European Public Administration Network (EUPAN) introduced this tool on the principles and philosophy of TQM and Public Management. The CAF is available for free and it is inspired by the European Foundation for Quality Management (EFQM) model, sharing the same 9 criteria. According to fundamental European guidance, all processes of Public Organizations must be part of a quality system, therefore, the implementation of the CAF, in addition to the use of other systems and quality tools, is a topic of first priority for the administrative transformation and the improvement of the Public Sector.

The essence of the CAF use is the continuous administrative improvement through appropriately designed actions or measures. The CAF constitutes a complete study of the structure and function of one Public Organization at a defined point of time. The process of self-assessment is based on real facts and evidence-based views for each criterion/subcriterion. The employees of the organization can perform the assessment themselves, without support from external partners.

The implementation of the CAF is a continuous process, since the results from one assessment should lead to the compilation of a plan with improvement actions, which, after their implementation, are re-assessed based on the same tool, in order to achieve continuous administrative improvement.

Public Organizations can implement the CAF either in their entirety or in specific divisions, yet always as a single tool and never in fragments, with the selective use of specific criteria and subcriteria.

ORIGIN AND DEVELOPMENT OF THE CAF

Public Administration throughout Europe, more than ever in our days, is asked by society to prove and improve the value it brings as far as the maintenance and further development of the societal well-being are concerned. In times of socio-financial austerity, the effectiveness of the public policies, the organizational adequacy and the quality of public services constitute factors of vital importance, which define the response to the changing needs and expectations of citizens and enterprises (Dimitriou and Archontas, 2015).

In the countries-members of the European Union, Public Administration is trying to meet all these societal requirements and has undertaken many initiatives for the implementation of new techniques and methods, aiming at improving its effectiveness, performance, as well as its financial and societal responsibility. To this direction different approaches have taken place in all types of Public Organizations and sectors of public responsibility, at European, national, federal, regional and local level. One of the key factors that affected the results of these initiatives was the lack of a coherent and sustainable approach (Michalopoulos, Polykratis and Dimitriou, 2017).

In 1998 from discussion among the General Managers of Public Administration of countries-members within EUPAN, the need for a common European quality framework arose, to be used across the Public Sector as a self-assessment tool. It was, therefore, decided that this quality framework be jointly developed under the auspices of the Innovative Public Services Group (IPSG), an unofficial working group from experts at national level, established by General Managers of EUPAN.

The first CAF edition was created in 1998 and 1999 from IPSG with the support of EFQM, Speyer Academy and the European Institute of Public Administration (EIPA). Speyer Academy had established the homonymous quality award for the Public Sector in German speaking European countries (Engel, 2002).

The CAF standard was implemented in 2000 during the 1st European Quality Conference in Lisbon. In 2001 in Maastricht, Netherlands the European CAF Resource Center was established in EIPA, as a center of specialization for the CAF implementation with the aim to train, consult and support countries members of the European Union in promoting and further enhancing the CAF.

The first two years of the implementation of CAF were evaluated by a study on its use. The results of the study led to the improved CAF 2002 edition, presented at the 2nd European Quality Conference in Denmark. A further study on the CAF use in 2005 indicated a number of areas requiring further improvement. Such improvements were the increase of the coherence and the simplification of the tool, the increase of user-friendliness with the elaboration of examples and special vocabulary, the development of a better scoring system for specific users and the incorporation of guidance documents about benchlearning. Therefore, the CAF was improved for the second time in 2006 and its new edition, the CAF 2006 edition, was presented at the 4th European Quality Conference in Finland. In 2009 and

2010 the establishment of a process of external feedback on the CAF use followed, along with a special edition for the teaching sector, respectively (Staes et al., 2011).

The most recent edition of CAF is this of year 2013, with the incorporation of changes that arose from observations collected from 400 users of the tool and its national correspondents in the countries-members of the European Union. With this revision, the tool improved significantly, with aim the benefit of all stakeholders of the Public Sector in general and more specifically of citizens (Michalopoulos, Polykratis and Dimitriou, 2017). For example, concepts like the users' orientation, public performance, innovation, ethics, effective collaboration with other organizations and social responsibility have been developed in depth, creating new possibilities for further development of the Public Sector organizations (Dimitriou and Archontas, 2015) (Table 1).

Table 1. The development of CAF

Year	Event
1998	Agreement on the development of the CAF within EUPAN
2000	CAF Implementation
2001	Foundation of European CAF Resource Center in EIPA Institute (Maastricht, Netherlands)
2002	First revision of the standard: Implementation of CAF 2002 edition
2006	Second revision of the standard: Implementation of CAF 2006 edition
2009	Implementation of external feedback process
2010	CAF edition specialized for teaching sector
2013	Third revision of the standard: Implementation of CAF 2013 edition

As far as the adoption of the tool is concerned, 59 European countries have currently implemented the CAF, having in total 3.989 registered users (EIPA, 2019).

OBJECTIVE OF THE CAF STANDARD

The CAF can act as a catalyst for an integrated improvement process within one Public Organization and has five basic objectives (EIPA, 2019) (Dimitriou and Archontas, 2015):

- To introduce Public Organizations in the excellence culture and the TQM principles,
- To guide them gradually to an integrated quality cycle, which consists of the Deming Cycle stages,
- To enable the self-assessment of one Public Organization and support it in diagnosing improvement areas and taking the appropriate actions,
- To act as a bridge between the different standards used for quality management in both Public and Private Sectors &
- To enable the bench learning among different organizations of the Public Sector

The organizations that implement the CAF are aspired to achieve excellent performance. The effective use of the CAF should lead to further development of this culture of excellence within the organization in a short time period.

STRUCTURE OF THE CAF STANDARD

According to the CAF, the excellent results in terms of organizational performance, citizens/customers' satisfaction and society's satisfaction depend on leadership, planning/design, human resources, partnerships, resources, as well as administrative processes.

The CAF is based on 8 basic principles, the so called "Excellence Principles". These principles make the difference between traditional, bureaucratic, Public Organizations and Public Organizations oriented towards Total Quality (Dimitriou and Archontas, 2015).

These principles are the following (Dimitriou and Archontas, 2015) (EIPA, 2019):

1. *Orientation towards results:*

The organization focuses on results, for the benefit of all interested parties (Public Authorities, citizens/customers, partners and human resources of the organization) in conjunction with the objectives set.

2. *Focus on citizen/customer:*

The organization focuses on the needs of both current and potential citizens/customers, promoting their active participation in the development of its products and services and the improvement of its performance.

3. *Leadership and consistency of purpose:*

This principle combines leadership that has vision and inspiration with purpose, which remains consistent in a changing environment. The leadership clearly establishes the mission, vision and values. In addition, it creates and maintains an internal environment in which human resources have the possibility to participate fully to meet the objectives of the organization.

4. *Management through processes and facts:*

The desired outcome comes successfully when relevant resources are managed as process and the effective decisions are driven by the analysis of facts and information.

5. *Development and participation of human resources:*

Human resources at all levels constitute the essence of the organization. The full participation of employees allows the use of their skills for the benefit of the organization. The personnel's contribution should be maximized through their development and participation, as well as through the creation of a working environment of common values, trust, transparency, empowerment and recognition.

6. *Continuous learning, innovation and improvement:*

The excellence constitutes a challenge for the current status and activates change through continuous learning. Therefore, continuous improvement should constitute a permanent objective of the organization.

7. *Development of partnerships:*

The organizations of the Public Sector need other Public Organizations to meet their objectives. Consequently, they should develop and maintain partnerships that add value, through a relationship of interdependence.

8. *Corporate social responsibility:*

Public Organizations must own their part of social responsibility. This means that they must respect ecological sustainability and try to meet the high expectations and requirements of the local and international community.

The CAF standard incorporates in its structure the Excellence Principles. Each of the principles is consisted by 4 maturity levels. The organization will reach these levels gradually during its course towards excellence through an integrated Quality Cycle, (Deming Cycle/Plan- Do- Check- Act, PDCA) (Figure 1).

Source: Encyclopedia of Production and Manufacturing Management, 2000.

Figure 3. The Deming Plan, Do, Check, Action (PDCA) cycle.

Source: Dimitriou and Archontas, 2015.

Figure 4. The CAF model.

The CAF has 9 criteria that represent the key aspects that need to be taken into account in the analysis of any organization. There are 5 criteria-enablers (Leadership, Strategy & Planning, Human Resources, Partnerships & Resources and Processes) and criteria-results (Results oriented to Citizen/Customer, Results oriented to Human Resources, Results oriented to Society and Key Performance Results) (EIPA, 2019). The criteria-enablers cover what the organization does, while the criteria-results cover what the organization achieves. With the conduct of a self-assessment, the Public Organizations can identify in their function, as well

as in their aspiration for desired results, areas for improvement (Tomazevic, Seljak and Aristovnik, 2014) (Figure 2).

The 9 criteria of the standard are further analyzed in 28 subcriteria, which identify the main issues that need to be addressed when a Public Organization is assessed. Each of these subcriteria comprises a series of examples (EIPA, 2019). These examples reflect a large number of successful practices across Europe. Despite the fact that not all criteria are applicable to all organizations, many of these require special attention during the self-assessment. The incorporation of the conclusions from the assessment of the criteria-enablers and the criteria-results into the administrative practices constitutes the never-ending cycle of innovation and learning, which accompanies organizations on their way to excellence (Dimitriou and Archontas, 2015).

Each organization can adjust freely the CAF to its specific conditions or even exceptional circumstances, yet with all 9 criteria and 28 subcriteria, as presented in Table 2:

Table 2. The CAF criteria

1st Criterion: Leadership	It assesses the way with which people at the helm and managers shape the mission of one Public Organization (P.O.), facilitate its fulfillment and contribute to the realization of the vision. It includes 4 sub-criteria.
Sub-criterion 1.1	The Leadership provides one clear direction of the P.O., developing vision, mission and values.
Sub-criterion 1.2	What the Leadership does to develop and implement a performance management system and changes.
Sub-criterion 1.3	What the Leadership does to encourage, support employees and act as a role model.
Sub-criterion 1.4	How the Leadership manages the relations with the politicians and the rest groups of interest to ensure common responsibilities.
2nd Criterion: Strategy & Planning	It assesses the way the P.O. implement its mission through one specific strategy oriented towards the groups of interest and with the support of public policies, programs, processes, etc. It includes 4 sub-criteria.
Sub-criterion 2.1	What the P.O. does to collect information regarding the current or future needs of the parties involved in its function.
Sub-criterion 2.2	What the P.O. does to develop, revise and update its strategy and planning taking into consideration the needs of all the involved parties in its function and the available resources.
Sub-criterion 2.3	What the P.O. does to implement strategy and planning throughout the organization.
Sub-criterion 2.4	What the P.O. does to design, implement and update its program for modernization and innovation.
3rd Criterion: Human Resources Management	It assesses the way a P.O. manages and develops the knowledge and skills of its personnel. It includes 3 sub-criteria.
Sub-criterion 3.1	What the P.O. does to program, manage and improve human resources with transparency in relation to its strategy and planning.
Sub-criterion 3.2	What the P.O. does to determine, develop and make use of employees' capabilities, harmonizing individual objectives with organizational ones.
Sub-criterion 3.3	What the P.O. does to involve employees by developing open dialogue and empowering them, supporting their well-being.
4th Criterion: Partnerships & Resources	It assesses the way the P.O. designs and manages the external relationships and the internal resources in order to support its policy, strategy and the effective function of its processes. It includes 6 sub-criteria.
Sub-criterion 4.1	What the P.O. does to develop and implement basic relationships of partnerships.

Table 2. (Continued)

Sub-criterion 4.2	What the P.O. does to develop and implement partnerships with citizens/customers.
Sub-criterion 4.3	What the P.O. does to manage finances.
Sub-criterion 4.4	What the P.O. does to manage information and knowledge.
Sub-criterion 4.5	What the P.O. does to manage technology.
Sub-criterion 4.6	What the P.O. does to manage its facilities.
5th Criterion: Management of Processes & Changes	It assesses the way the P.O. manages and improves the processes in order to support its strategy and satisfy its citizens/customers.
Sub-criterion 5.1	What the P.O. does to determine, design and continuously improve its processes.
Sub-criterion 5.2	What the P.O. does to develop and provide services and products oriented to the citizen/customer.
Sub-criterion 5.3	What the P.O. does to develop innovative processes with the citizens' participation.
6th Criterion: Citizens-Oriented rEsults	It assesses the results of the P.O. in relation to the satisfaction of the external and internal customers. It includes 2 sub-criteria.
Sub-criterion 6.1	Results of the citizens'/customers' satisfaction surveys.
Sub-criterion 6.2	Indicators regarding evaluations for citizens/customers.
7th Criterion: Human Resources-oriented Results	It assesses the results that the P.O. achieves in relation to the satisfaction of its human resources. It includes through 2 sub-criteria.
Sub-criterion 7.1	Results of human resources' satisfaction survey.
Sub-criterion 7.2	Indicators of effectiveness of human resources.
8th Criterion: Society-Oriented Results	It assesses what the P.O. achieves for the satisfaction of the needs and expectations of society for topics like the quality of life, the maintenance of global resources, etc. It includes 2 sub-criteria.
Sub-criterion 8.1	What results has the P.O. achieved to address the needs of society in relation to the results of social surveys, as the involved citizens perceive them.
Sub-criterion 8.2	What results has the P.O. achieved to meet the society's needs in relation to indicators of social performance established by the P.O.
9th Criterion: Key Performance Results	It assesses what the P.O. achieves in relation to its constitutional mandate and its defined objectives, as well as in relation to the satisfaction of the needs and expectations of all parties that have a financial interest or participate in the P.O. It includes 2 sub-criteria.
Sub-criterion 9.1	External results. Output- results in relation to the objectives.
Sub-criterion 9.2	Internal results.

Source: (Efkarpidis, 2016).

INTERCONNECTED FUNCTIONS IN THE CONTEXT OF THE CAF STANDARD

The holistic approach of the CAF does not only suggest that one Public Organization's functions are thoroughly assessed but also that all integral elements of the organization are interdependent. The following remarks can be made:

- There is a cause-effect relationship between the left part (conditions- causes) and the right part (results- consequences) of the standard (Figure 2).
- There is a holistic relationship among causes (conditions).

The verification of the interconnection between cause-effect is of fundamental importance for the self-assessment, in the context of which the organization must always check the consistency between certain result or a series of similar results and the evidence arisen from the relevant criteria and sub-criteria regarding conditions. This consistency is sometimes difficult to verify because, due to the holistic character of the organization, the different causes (conditions) interact between each other during the delivery of results. Since the integrity of results is defined largely by the type and intensity of the relationships between conditions, these relationships must be investigated during the assessment. In fact, the intensity of these relationships differs among different organizations and their nature defines largely the quality of the organization.

Apparently the relationships are not limited to the level of criteria. Quite often substantial interactions- relationships exist at the level of sub-criteria.

COMMON EUROPEAN VALUES OF THE PUBLIC SECTOR

The CAF is designed specifically for the Public Sector and this is the differentiating point from the EFQM standard.

Quality in the Public Sector present some unique features compared to the Private Sector, taking into account the basic conditions of the European socio-political and administrative culture (EIPA, 2019).

These conditions are the legitimacy (democratic and parliamentary) and the state of justice and ethics, which are based on common values and principles, like transparency, accountability, participation, diversity, equality, social justice, solidarity, collaboration and the relationships with the stakeholders (EIPA, 2019). All the above constitute elements to be taken into account during the assessment.

Although the CAF focuses mainly on the assessment of the performance of the administration and on the identification of the organizational causes that make improvement possible, the ultimate goal is to contribute to good governance.

THE IMPORTANCE OF EVIDENCE AND MEASUREMENTS OF THE CAF

The self-assessment and the improvement of the Public Organizations become difficult without reliable information from their different functions. The CAF supports Public Organizations in the collection and use of information, yet quite often this information is not available during the first self-assessment. For this reason, the CAF is often seen as measurement that starts from scratch, indicating the important areas for the initiation of the measurement. As long as the Administration is under a process of continuous improvement, information will be increasingly collected and managed in a systemic and gradual manner both in the internal and external environment (Dimitriou and Archontas, 2015).

COMMON ADMINISTRATIVE LANGUAGE AND GLOSSARY OF THE CAF

Many Public Organizations are facing difficulties in understanding Management terminology. The CAF creates a common language allowing the organization's personnel and leadership to discuss about organizational topics in a constructive way. This simple and understandable language by all public employees promotes the dialogue and the bench learning among Public Administrations at European level (Dimitriou and Archontas, 2015).

THE ROLE OF THE ASSESSMENT SYSTEM IN THE CAF

Although the identification of the strengths, the areas for improvements and the relevant improvement actions constitute the most important results of the self-assessment, the CAF scoring system plays an equal special role (Dimitriou and Archontas, 2015).

The scoring of each criterion and sub-criterion of the CAF standard has 4 main objectives:

- To provide an indication for the direction that the Public Organization shall follow as regards improvement actions,
- To measure the improvement of the Public Organization,
- To identify successful practices, as these are determined by the high scores for the conditions and the results &
- To assist in finding the appropriate stakeholders from whom the Public Organization can learn.

SUPPORT IN THE USE OF THE CAF

In 2001 with decision of the responsible General Managers for the Public Administration, a network of national representatives for the CAF was established, as well as the CAF Resource Center, as previously mentioned. This network is responsible at European level for the development and the monitoring of the standard. In addition, it studies new tools and strategies for the promotion of the CAF. CAF Resource Center operates in EIPA in Maastricht, Netherlands and is responsible for the coordination of the network. In addition, it manages the CAF webpage, which is the access point to all CAF-related information and other TQM topics.

In the countries-members of European Union the national representatives take the right initiatives to encourage and support the use of the standard in their countries. The activities of the Center cover a broad spectrum, ranging from the creation of national centers of data management to the construction of specialized web portals and from national or regional projects or programs to national awards or quality conferences based on the CAF standard (Dimitriou and Archontas, 2015).

THE PROCESS OF EXTERNAL FEEDBACK

In order for the Public Organizations to implement the CAF successfully, there is a formal process to provide feedback from the external environment on the overall quality management with the CAF use. This external feedback process, implemented on a voluntary basis, aims at supporting even more the CAF users on their way towards quality, making their efforts visible within and outside the organization. This feedback process relates to the self-assessment process, as well as to the broader vision of the organizations to achieve excellence over time.

The external feedback process aims at achieving the following objectives:

- To support the quality of the CAF implementation and the impact on the organization,
- To investigate whether the organization adopts the TQM principles, as a consequence of the CAF implementation,
- To support and empower the feeling of enthusiasm with continuous improvement inside the organization,
- To promote the assessment and the bench learning from similar organizations,
- To reward the organizations that have started their course towards continuous improvement for achieving excellence in an effective manner, without criticizing their current quality level &
- To enable the participation of the CAF users at the level of excellence of the EFQM model

The process of the external feedback is based on the following 3 pillars:

- Pillar 1: Self-assessment process,
- Pillar 2: Improvement actions process &
- Pillar 3: Maturity of the organization towards TQM

The organizations that have used the CAF effectively may assume the title of “Effective CAF user” given for a duration of 2 years. The process of external feedback and the previous title are at the discretion of countries-members, which create the practical details having as basis a commonly agreed frame but at their own pace. The organizations that wish to submit an application for the title above have to be informed in advance if this possibility exists in their countries (Dimitriou and Archontas, 2015).

ADVANTAGES OF THE CAF STANDARD

The CAF has the following advantages (Michalopoulos, Polykratis and Dimitriou, 2017):

1. It constitutes a first attempt to manage the diversity of the administrative systems of the countries-members of the European Union, setting common criteria and a single

assessment method, so that its conclusions be comparable, commonly accepted and utilizable and common policies be designed if and when conditions allow for it.

2. It allows the development of contacts, communication and cooperation among the agencies of the Public Administration of the countries-members of the European Union, as well as the exchange of experiences for topics of administrative organization and function.
3. It creates the preconditions for the implementation of a broader plan to establish the European Quality Award in the Public Administration.
4. It significantly contributes to the introduction of the philosophy and the concepts of TQM and of Public Management into the Public Organizations.
5. It enforces the participation of the staff of one Public Organization in the process of the assessment of its function, since in principle it is about a self-assessment method.
6. It constitutes a holistic study of the structure and function of one Public Organization at one specific point of time. The self-assessment process is based on real facts and justified conclusions for each aspect under evaluation and it can be carried out by the employees of the Public Organization themselves, without assistance from external partners.
7. Its implementation is a continuous process, since the conclusions of one assessment lead to the implementation of a plan with actions for the improvement of the administrative function, which after their implementation, are re-assessed based on the CAF again.
8. The CAF does not concern the assessment of the public policies that one Public Organization applies, but its administrative function.
9. The CAF is linked in no way with the performance assessment of the personnel of the Public Organization at any hierarchical level of responsibility.
10. The CAF may be implemented either to the whole Organization either to individual units, yet always in an integrated way, as single system and not in a fragmented way with the selective implementation of some criteria and sub-criteria.

CONCLUSION

Concluding on the above observations about the CAF, its implementation is suggested for the Public Organizations, so that they can use a tool for the improvement of their administrative capacity, which belongs to them and they do not necessarily need to refer to external sources for the implementation of some similar integrated methodology.

Chapter 533

**BRAZILIAN RATTLESNAKE
(*CROTALUS DURISSUS LINNAEUS 1758*) IN
THE ATLANTIC FOREST OF RIO DE JANEIRO
STATE: A CASE OF BIOLOGICAL INVASION
OR A RED ALERT TO PUBLIC HEALTH?**

ABSTRACT

Crotalus durissus is the snake species within its genus which covers the largest geographic distribution, reaching almost the entire South American territory. This species is widely dispersed and adaptable to open and anthropized environments. *C. durissus* is increasingly entering areas which once belonged to the Atlantic Forest biome and were covered by Ombrophilous (broadleaf) Forest. The main reason this species is establishing in this new environment is due to Atlantic Forest deforestation; initially to establish coffee and sugarcane plantations, and later to establish pastures for livestock. The new environment has become similar to the *Cerrado* biome, which was the original habitat of *C. durissus* in southeastern Brazil. *Cerrado* is one of the most representative biomes in the State of Minas Gerais, and from which several *C. durissus* individuals have migrated from towards the State of Rio de Janeiro. With this new panorama, the species has started

* Corresponding Author's Email: pontesjal@hotmail.com.

to cause sanitary and possibly ecological problems such as an increase in number of local residents injured by snakebites (affecting the distribution of snake anti-venom in health posts, and predation and competition with native species). In this chapter, we aim to review and analyze the past and present view of *C. durissus* distribution in the State of Rio de Janeiro through scientific literature review and consultations in the biological collections of the Rio de Janeiro National Museum and Vital Brazil Institute. We also correlated its distribution to the time it took to advance into the State.

Thus, we found *C. durissus* records in 13 municipalities and 11 of them were new records for the State. There was no prior confirmation about the presence of the species in these sites, evidencing that it is increasing its geographical distribution mainly toward degraded areas in the State of Rio de Janeiro. The new *C. durissus* records indicate that it is spreading into Rio de Janeiro through three routes: *Paraíba do Sul* River Valley, mountainous region, and *Serra da Bocaina* in the municipality of *Paraty*. The new rattlesnake records were associated to the Atlantic Forest degradation in these locations. The expansion in the distribution area of this poisonous snake into densely populated areas is expected to increase the number of snakebite accidents, which will require greater production of snake anti-venom. In addition, its expansion is expected to have ecological impacts on the native fauna. More attention should be given to this issue in the State of Rio de Janeiro in order to prevent the species from advancing into new areas.

Keywords: bioinvasion, environmental degradation, geographic distribution, rattlesnake

INTRODUCTION

The planet's Neotropical Region shelters invaluable and great biological diversity due to vicarious effects. Within them there are three main effects which can be drawn: the emergence of the Andes; the Panama isthmus; and the constant climatic changes during and after the Pleistocene epoch, which occurred approximately 1.8 million years ago (e.g., Wing and Sues, 1992, 327-416; Mittermeier et al., 2005; Wüster et al., 2005, 1095-1108).

This last event is the most known and controversial Atlantic Rainforest speciation model known as the Pleistocene Refuge hypothesis (Haffer 1969, 131-137; Vanzolini and Williams 1981, 251-255), during which the Amazon had its dimensions reduced due to climatic fluctuations, specifically at the end of the Pleistocene and Pliocene epoch (Quijada-Mascareñas et al., 2007, 1296-1312). This fact resulted in intense fragmentation of the biome and created geographical barriers which favored allopatric biological diversity formation (Haffer 1969, 131-137; Haffer and Prance 2001, 579-607).

Commonly known as rattlesnakes, serpents of the *Crotalus* genus had their speciation well evidenced with the occurrence of only one species on the south portion of the American continent *Crotalus durissus* (Linnaeus 1758). However, this species has the greatest geographical distribution among the genus, possessing 11 described subspecies (Campbell and Lamar 2004, 539-547), among which six can be encountered in Brazilian territory (Costa and Bérnills 2018, 57). These Brazilian subspecies are: *Crotalus durissus durissus* (Linnaeus 1758), described in the State of Amapá; *Crotalus durissus ruruima* (Hoge 1966), described in the State of Roraima; *Crotalus durissus cascavella* (Wagler in Spix 1824), registered in the States of Maranhão, Piauí, Ceará, Rio Grande do Norte, Paraíba, Pernambuco, Alagoas, Sergipe, Bahia, and Minas Gerais; *Crotalus durissus marajoensis* (Hoge 1966), recorded at Marajó Island (Pará); *Crotalus durissus collilineatus* (Amaral 1926), found in Tocantins,

Mato Grosso, Mato Grosso do Sul, Goiás, Distrito Federal, Minas Gerais, and São Paulo; and lastly, *Crotalus durissus terrificus* (Laurenti 1768), found in Tocantins, Mato Grosso, Minas Gerais, Rio de Janeiro, São Paulo, Santa Catarina, Paraná, and Rio Grande do Sul (Hoge and Romano 1978/79, 491; Campbell and Lamar 2004, 539-547; Dos-Santos et al., 2005, 958-961; Costa and Bérnils 2018, 29). The species inhabits almost all of the Brazilian biomes, especially those with open and dry vegetation such as the Brazilian *Cerrado* (Brazilian Savannah), but they do not inhabit humid tropical forests such as the Amazon and the Atlantic Rainforest. *Crotalus d. terrificus* is the only subspecies with recent records in the State of Rio de Janeiro in the Atlantic Forest domain (e.g., Campbell and Lamar 2004, 539-547; Bastos et al., 2005, 812-815; Costa and Bérnils 2018, 29) (Figures 1 and 2).

Figure 1. Geographical distribution of *Crotalus durissus* (Linnaeus 1758) in South America (black dots), with locality type (white dot). Map by Campbell and Lamar (2004).

Figure 2. *Crotalus durissus terrificus* (Laurenti, 1768) ♀ in an area of Atlantic Forest, Paraty/Cunha (Rio de Janeiro/São Paulo), Brazil. Photography by Jorge Pontes 2016.

C. durissus is commonly found in areas below 1,000 m altitude, but there is a recorded registry of 2,300 m at Sandia, Peru (Mijares-Urrutia and Arends 2000, 1-30). The species presents variable dorsal coloration in different regions in Brazil (Campbell and Lamar 2004, 539-547). It has the ability to colonize insular areas such as Aruba, and the climate changes and vegetal cover modifications during the Pliocene and Pleistocene epochs had an effect on the species distribution in South America, reaching pastures and coastal open vegetation (Mijares-Urrutia and Arends 2000, 1-30; Campbell and Lamar 2004, 539-547).

Exotic and invasive species are currently one of the greatest causes of native species extinction around the globe (e.g., Gurevich and Padilla 2004, 470-474; Pimentel 2011, 1-7). In competition for resources or by predation of native species, invasive exotic fauna grow rapidly in association with human occupation and other actions (e.g., Pimentel 2011, 1-7; Rocha and Bergallo 2012, 1-2). Several serpent species have become environmental, economic and public health problems in some places around the world (e.g., Jorge and Ribeiro 1992, 347-354; Duarte and Eterovic 2003, 126-135; Warrel 2004, 709-761; Bergstrom et al., 2009, 73-81). Public health problems in Brazil are aggravated by the reduction in the availability of snake anti-venom in health posts, including Rio de Janeiro State (Cardoso and Wen 2003, 3-5; Citeli et al., 2018, 123-124).

The species was not found in the State of Rio de Janeiro before 1940 because this region was not part of its natural geographic distribution and the forest matrix was a barrier for the rattlesnake to enter into the State (Melgarejo 2003, 52-53; Melgarejo 2013, 59; present study). However, *C. durissus* is becoming an invasive species in the Atlantic Rainforest biome, mostly due to deforestation and its aptness to adapt to open surroundings and anthropized environments such as man-made fields and pastures (Marques, Eterovic and Sazima. 2019, 44; Bastos et al., 2005, 812-815; Wüster et al., 2005, 1095-1108; present study). Its oldest record in the institutional collection in Rio de Janeiro State dates from 1988 in the municipality of Itatiaia (present study).

Ever since this time, *Crotalus durissus* has been taking advantage of its new environment, which (despite anthropic influences) resembles its original habitat, the *Cerrado*. Once established in its new habitat, the species begins to not only affect the native fauna, but also the local human population, thereby causing new snakebite accidents being recorded in places in which they did not previously occur. Therefore, this becomes a problem in the Health Ministry's snake anti-venom distribution directive for the incident regions, as *Crotalus durissus* is responsible for 7.7% of the snakebite accidents in Brazil (Duarte and Menezes 2013, 1-4; Melgarejo 2013, 59).

Although this percentage seems relatively low, the mortality rate is 1.84% (Pinho and Pereira 2001, 24-29). This is higher than deaths caused by the *Bothrops* genus (0.45% mortality rate) which is responsible for 90.6% of snakebite incidents in Brazil (Luna and Silva 2011, 130). The remaining incidents of medical importance are attributed to serpents of the *Lachesis* genus (known in Brazil as “*sucurucu*,” “*pico-de-jaca*,” and “*surucutinga*”), accountable for 1.4% of incidents, and the *Micrurus* genus (“*corais-verdadeiras*”), responsible for approximately 0.4% of the incidents (Pinho and Pereira 2001, 24-29).

In view of the above, in this chapter we aimed to compile the most recent records of the occurrence of *Crotalus durissus* in Rio de Janeiro State, as well as to know the situations in which the species advance in its area of occurrence. More specifically, we aimed to clarify when the species began to spread to new municipalities in Rio de Janeiro State, particularly in

the most populous regions, which might become a leading factor for an increase in snakebite accidents.

METHODS

Literature Review

A bibliographic revision was performed in order to identify articles and further publications regarding biogeography, ecology and registry of the *Crotalus durissus* species in the municipalities of the Rio de Janeiro and neighboring States. The criteria used to choose these articles were the keywords regarding the *Crotalus* genus, invasion specimens, snakebites in Rio de Janeiro State, and seasonal activity. Papers used in this study were mainly compiled in academic articles which comprehend *Crotalus durissus* distribution inside or outside of Rio de Janeiro State. Google Scholar, Scielo, ScienceDirect and Web of Science databases were used to search for the articles.

Collection Review

We performed a review on the herpetological collection of the Rio de Janeiro National Museum (MNRJ) and the Vital Brazil Institute, Niterói (IVB) to compile rattlesnake records in the State of Rio de Janeiro and vicinity between 1980 and 2019. The inventory books of the visited institutions contain capture data, local, rostrum-cloacal length (RCL), gender, acronym (record number) and other additional observations. The review at the Vital Brazil Institute was done via digital inventory books using a filter to solely compile the State of Rio de Janeiro and vicinity, as well as individuals which had been run over by vehicles. It was not possible to identify the gender of the animals or the RCL for data collected at the Vital Brazil Institute because the Biological Collection Division was relocated and disorganized at the time of consultations.

A physical inventory book was rearranged at the National Museum using the same filters as in the aforementioned review. A great deal of the deposited specimens in the Museum were collected from roads and their physical condition presented damage to such an extent that the RCL had to be taken by attaching body parts (head, body, and tail) with the use of metric tape. Specimen gender discrimination was performed by visualizing the reproductive organs (when possible) or by consulting the inventory books. We have also included the date and place of collection in the review, and other relevant information observed in the field.

The data gathered in the institutions were processed using Microsoft Excel® software, from which graphics and lists were elaborated using municipality's occurrence as criteria.

Maps

We mapped the invasion of *Crotalus durissus* in municipalities of the State of Rio de Janeiro from 1988 to 2019 through bibliographic data and collection records. The map was

generated via ArcGIS software, entering the geographic coordinates (UTM, SIRGAS 2000) and indicating the species occurrences. A breakthrough in the species distribution in the State of Rio de Janeiro was created by organizing occurrences by decades. Some records, more specifically the roads sampled ($n = 10$), did not have additional information about the exact collection point. Thus, we chose to perform a coordinate approximation according to the indicated locations. When the registry only mentioned the municipality name in the inventory books, we used the central point (coordination) of the city as reference.

RESULTS

We found 77 records of *C. durissus* between 1988 and 2019 for the State of Rio de Janeiro: 58 records were found in the Vital Brazil Institute, 15 records in the National Museum (Figure 3), and four other casual encounters: two in the municipality of Paraty, one in Cunha, and another in Miguel Pereira. The records found in the Vital Brazil and National Museum institutions comprised 13 municipalities, in which eleven were new occurrences (*Nova Friburgo*, *Miguel Pereira*, *Paraty*, *Petrópolis*, *Vassouras*, *Itatiaia*, *Conservatória*, *Levy Gasparian*, *Paraíba do Sul*, *Três Rios*, and *Volta Redonda*). Of the 77 records, 54.5% ($n = 42$) were found in the municipality of *Valença*. An other 9.0% ($n = 7$) were registered in *Três Rios*, 9.0% ($n = 7$) in *Rio das Flores*, 7.8% ($n = 6$) in *Paraíba do Sul*, 3.9% ($n = 3$) in *Levy Gasparian*, 2.6% ($n = 2$) in *Paraty*, 2.6% ($n = 2$) from the BR 040 highway, and 1.3% ($n = 1$) in *Conservatória*, *Volta Redonda*, *Itatiaia*, *Nova Friburgo*, *Petrópolis*, *Miguel Pereira*, *Cunha*, SP/*Paraty*, RJ (border municipalities) and *Vassouras*.

Figure 3. *Crotalus durissus* specimens (n) collected in the State of Rio de Janeiro between 1988 and 2019 and deposited at the Rio de Janeiro National Museum (Rio de Janeiro City) and Vital Brazil Institute collection (Niterói City).

Among the examined specimens, seven were identified at the subspecies level (*Crotalus durissus terrificus*). All of them were found in the municipality of *Rio das Flores*. The number of *C. durissus* collected in the State of Rio de Janeiro and deposited in the institutional collections varied over a period of 31 years (between 1988 and 2019) (arithmetic average 2.3 ± 3.2 individuals per year). Most specimens were collected in the early 1990s and this may be related to collection activities carried out at the *Sítio Divina Providência*. The site is in the municipality of *Valença* and is bordered by the State of Minas Gerais.

A total of 10 *C. durissus* individuals were registered at the BR-040 highway nearby the cities of *Matias Barbosa*, MG ($n = 4$), *Levy Gasparian*, RJ ($n = 1$), *Juiz de Fora*, MG ($n = 2$), *Simão Pereira*, MG ($n = 2$) and *Lima Duarte*, MG ($n = 1$). The oldest record was from 1988 at the *Represa do Funil* in the municipality of *Itatiaia*, albeit the most recent records were found between 2018 and 2019 in *Miguel Pereira*, *Nova Friburgo*, *Petrópolis* and *Três Rios*.

We observed that another *C. durissus* was captured in 2006 in *Rio das Flores* after a 10-year gap. There were six new registries found in 2007. Furthermore, there was a considerable number of these serpents encountered at the roadside ($n = 10$) in the 2010 decade, usually run over by vehicles.

Although *Paraty* has been indicated as a new viable route for southern invasion into the State of Rio de Janeiro, all recent occurrences of *C. durissus* have been recorded in the Rio de Janeiro Metropolitan Region. In addition, an individual was registered in 2019 in the *Miguel Pereira* municipality by Murilo Vicente (personal communication). The taxonomic identity of this specimen was confirmed through photographic evidences (Figure 4).

Figure 4. A *Crotalus durissus* (Linnaeus 1758) individual was registered in the municipality of *Miguel Pereira*, Rio de Janeiro State. Photograph by Murilo Vicente on March 04, 2019.

In 2016, during a study by researchers from the Rio de Janeiro State University in *Paraty*, three *C. durissus* were registered at the *Serra da Bocaina* National Park. One of those individuals was run over on the border of the States of Rio de Janeiro and São Paulo, in the municipality of *Cunha* (Figure 5).

Figure 5. *Crotalus durissus* (Linnaeus 1758) specimen being captured in the SP–171 highway, border of the municipality of *Cunha* (São Paulo State) and *Paraty* (Rio de Janeiro State), near *Serra da Bocaina* National Park. Photography by José Vitor Maciel, 2016.

We observed that the area of occurrence of the species increased between 1988 and 2019, and it is advancing towards the central region of the State of Rio de Janeiro. Advancement through municipalities and all records overlaps deforested and anthropized areas, mainly pasture and secondary vegetation in the early stages of regeneration (Figures 6 and 7).

Figure 6. (Continued).

Figure 6. Forest cover map indicating *Crotalus durissus* (Linnaeus 1758) registries by decade between 1988 and 2019 (a). The occurrence records were extracted from the Rio de Janeiro National Museum (Rio de Janeiro city) and Vital Brazil Institute (Niterói city) Collections. Advance in space and time of *C. durissus* records in the municipalities of Rio de Janeiro State (b).

Figure 7. Aspect of *Serra da Bocaina* on the border of Paraty (Rio de Janeiro State) and *Cunha* (São Paulo State) municipalities. Forest fragmentation and anthropic environments facilitate the entrance of *Crotalus durissus* (Linnaeus 1758) into Paraty, Rio de Janeiro State. Photography by Jorge Pontes, 2011.

DISCUSSION

The advancing area of *Crotalus durissus* occurrence was directly influenced by anthropic actions in the State of Rio de Janeiro, mainly due to deforestation which gave space to coffee and sugarcane plantations, and culminated in a reduction of the Dense Ombrophilous Forest to sparse forest fragments, making way for the serpent species incursion. Almost 80% of the Atlantic Rainforest domain has already been lost (Bastos et al., 2005, 812-815; Castro and Lardosa 2015, 6-27), and pasture areas for cattle ranching have been established in its place. According to Bastos et al., (2005), the presence of *Crotalus durissus* in these regions may be attributed to the great floods in the *Paraíba do Sul* River Basin which occurred in the 1950s and 60s. This argument seems questionable due to the fact that the species indicates its advance regardless of natural disasters, and it is believed that the advance is caused by occupancy of anthropic environments similar to the *Cerrado* biome, which were found at the Vale do Paraíba region due to farming exploitation (Costa and Clemente 2009, 57-65; Melgarejo 2013, 59).

Our study adds eleven new legal municipalities with the occurrence of *C. durissus* to the study by Bastos et al., (2005), where only *Valença*, *Rio das Flores* and *Resende* have some officially registered specimens, with the others being informal records. The records for the studied period (1988-2019) indicate that the species has been advancing to deforested areas and areas replaced by pasture or anthropic fields. This fact is also pointed out by Melgarejo (2003).

This advance form with a high concentration of records in the north of the State may be related to the high rates of land occupation by pasture, livestock and sugarcane plantations in established farms (Rocha et al., 2003, 3-32; Costa and Clemente 2009, 57-65). The advance of *C. durissus* may also be related to deforestation and the fire propagation cycle which lead to secondary vegetation (Tanizaki-Fonseca and Bohrer 2009, 81-90), and creates habitats and passageways for the entry and dispersion of the species.

In addition to the spatial records, the generated maps enable visualizing the expansion of the species to areas which were previously free from *C. durissus* invasion, such as *Miguel Pereira*, *Nova Friburgo* and *Petrópolis*. Interestingly, the aforementioned localities do not present proper climatic patterns for the natural habitat of serpent species (Campbell and Lamar 2004, 539-547; Melgarejo 2003, 52-53), indicating that rattlesnakes are expanding their distribution to colder and damper environments.

There was an increase in the number of rattlesnakes in the 2010s, especially in the highways linking Minas Gerais and Rio de Janeiro. However, another possible invasion route seems to have been established through *Paraty* because the region is vastly occupied by pasture and anthropic fields (Rocha et al., 2003, 3-32; Mittemeier et al., 2005; Santos et al., 2009, 41-56).

Population expansion of *C. durissus* seems evident in the interior of Rio de Janeiro State and throughout the central and coastal areas. Its occupation coincides with more populous areas where some municipalities will be considerably more affected than others. The species is in second place regarding snakebite accidents in Brazil (Araújo, Santa Lucia and Cabral 2003, 7) and the reduction in snakebite anti-venom production, health posts and the lack of organization regarding available information (Bochner and Struchiner 2002, 741-744; Citeli

et al., 2018, 123-124; Ministério da Saúde 2019) could mean an increase in the number of complications due to accidents and even more deaths.

The situation regarding the advance of an exotic species from another Brazilian region which was able to adapt to the Ombrophilous Forest domain is not only creating a concerning panorama for environmental conservation regarding the implications of biological invasion, but also to the healthcare system as a whole in Rio de Janeiro State.

ABSTRACT

The era of antimicrobial resistance is now upon us. Resistance problems are especially visible with hospitalized patients, as resistant infections readily spread among weakened hosts in close contact. But treatment choices are also diminished for some community infections, such as tuberculosis, pneumonia, and sexually transmitted diseases. Managing this new era in medicine is challenging, in part because we rely so heavily on antimicrobials. The problems are exacerbated by global travel, since resistance is readily disseminated. Calls to reduce consumption have raised general awareness and led to some reduction in the prevalence of resistance, but on a global level antimicrobial consumption remains high, both in agriculture and in human populations. Thus, antibiotic resistance will not disappear soon. Since new antimicrobials are becoming increasingly difficult to find, it is likely that we will need new strategies for suppressing resistance and for incentivizing the discovery and development of new antimicrobial therapies.

Keywords: antimicrobial, bacteria, resistance, tuberculosis, hospital infection

INTRODUCTION

In recent years, the problem of antimicrobial resistance has been recognized and addressed by international, regional, and national public health agencies, authorities, and

* Corresponding Author's Email: vijaymishra2@gmail.com.

professional societies (Carlet et al., 2012; Bell, 2014; Laxminarayan et al., 2014; Shallcross and Davies, 2014). Antibiotics have saved millions of lives and have enabled many other medical advances since their discovery and introduction into clinical practice. The worsening problem of antimicrobial resistance now jeopardizes many of these advances. However, action plans to minimize this threat have been developed by many public health agencies around the globe (CDC, 2013; Kessel and Sharland, 2013; Keown et al., 2014; Paphitou, 2013). This focus is likely to increase among public health agencies in the coming years. Several facets of the problem involve the relationship between human and animal use of antimicrobial agents (Laxminarayan et al., 2014; McIntosh and Dean, 2014). This chapter summarizes the components of the cost of resistance from a public health perspective and contrasts this perspective to other societal perspectives. It then reviews strategies at several different levels of responsibility, ranging from the patient care provider to international agencies. Finally, it considers appropriate public health responses according to the resources available for control.

In an era of globalization, antimicrobial resistance represents an international concern that demands a concerted effort from multiple health and industry sectors. Public health must be at the forefront of these efforts. Antimicrobial resistance is widely recognized as a complex international problem. Antibiotics have saved millions of lives and have enabled many other medical advances since their discovery and introduction into clinical practice. The worsening problem of antimicrobial resistance now jeopardizes many of these advances (Carlet et al., 2011; Carlet et al., 2012; Speck, 2013; Spellberg et al., 2013; Bell, 2014; Keown et al., 2014; Shallcross and Davies, 2014; Paphitou, 2013; Woolhouse and Farrar, 2014). The number of pathogens resistant to multiple classes of antimicrobials has increased worldwide (WHO, 2014).

There have been reports of infections with *Pseudomonas aeruginosa* and *Acinetobacter* species which are resistant to all available antibiotics (Paterson, 2006). Other pathogens, such as *Neisseria gonorrhoeae*, that were previously relatively easy to treat, are now becoming much more difficult to treat due to antimicrobial resistance (Ndowa et al., 2013). There is also evidence that resistant organisms that were previously confined to the acute care hospital setting are now sources of community acquired infections (Dantes et al., 2013). Resistance is not only an issue for bacterial pathogens like Staphylococci, Enterococci, *Escherichia coli*, *Klebsiella*, *Neisseria*, and *Mycobacterium tuberculosis* but also the problem of resistance is increasingly being recognized in nonbacterial pathogens like *Candida*, HIV, malaria, and influenza (WHO, 2014).

The worldwide increase in the prevalence of resistance is a concern because it threatens both the optimal care of patients with infections and the viability of current healthcare systems (DiazGranados et al., 2008). For individual patients, antimicrobial drug resistance has a clear impact on patient morbidity and mortality (Cosgrove, 2006; Neidell et al., 2012; CDC, 2013). Of concern for healthcare systems is the economic impact of resistance (McGowan et al., 2001; Roberts et al., 2009; White, 2011; Neidell et al., 2012). In the United States, resistance is especially costly for the healthcare system and for the third-party payers that support such systems (Roberts et al., 2009; Neidell et al., 2012). Costs are also burdensome for national-based healthcare programs (White, 2011). The incremental cost of caring for patients infected with resistant organisms has several aspects (Cosgrove, 2006; Roberts et al., 2009; Neidell et al., 2012). As the prevalence of resistance increases, physicians often substitute older and less expensive drugs for newer and more expensive

agents (Laxminarayan, 2014). Such costs in the United States are absorbed only in part by third-party payers, which often reimburse on the basis of head count, diagnosis related groups, or other formulas unrelated to specific services provided to an individual patient. Thus, most costs associated with resistant infections must be absorbed by the healthcare system itself (Laxminarayan and Malani, 2007). As the prevalence of drug resistant organism increases, these additional costs will mount and become a threat to the financial stability of local, regional, and national healthcare systems, many of which are already struggling to survive.

PUBLIC HEALTH AS A PERSPECTIVE ON RESISTANCE

Public health involves the population as a whole. It focuses on what we as a society do to assure conditions in which we can be healthy (Institute of Medicine, 1988). The goal of public health, the health of a population, can be distinguished from the goals of medical care, the health of a patient (McGowan, 2012). The public health goal, fueled by an aim of social good, is much broader in scope. It can encompass the health of neighborhoods, cities, countries, or even the entire world (McGowan, 2001). Using the public health perspective of health, a long time frame for evaluation is usually appropriate. Since antimicrobials can both prevent and treat infections in society, society considers them a valuable resource (Carlet and Pittet, 2013). As resistance diminishes this resource, a societal goal should be to minimize resistance and therefore to reduce the forces that produce resistance (Chaudhary et al., 2012; Kessel and Sharland, 2013; Carlet et al., 2014). All use of antimicrobials increases the likelihood of resistance developing (Woolhouse and Farrar, 2014). From a societal viewpoint, the use of antimicrobials to appropriately treat infections would be an appropriate rate of depletion of this valuable resource (Laxminarayan and Malani, 2007; Bartlett, 2011). Overuse or misuse of antimicrobials would be an inappropriately increased depletion of this resource (Bartlett et al., 2013). The costs of resistance from a public health perspective can be summarized as those resulting from treatment of patients infected with resistant organisms, those resulting from treatment of patients not infected with resistant organisms, and those resulting from antimicrobial use in agriculture, animal breeding, aquaculture, and industry.

The impact of antimicrobial resistance includes an increase in morbidity, mortality, and added costs for patients with resistant organisms. The added costs include those derived from the use of scarce healthcare resources: the care of patients with infections of resistant organisms, preventing transmission, maximizing appropriate empiric therapy, and resistance surveillance. In addition, excess loss of productivity and excess intangible costs such as patient and physician anxiety, pain, suffering, and inconvenience are also increased with antimicrobial resistance. Antimicrobial drug markets may also be affected by increasing resistance. Older, cheaper, and more narrow-spectrum drugs often become less useful, while the marketability of newer, more expensive, and more broad-spectrum drugs is favored (Van Boeckel et al., 2014).

Numerous studies have demonstrated that antimicrobial resistant organisms are associated with a higher morbidity and mortality than susceptible organisms. This has been shown for many different types of resistant organisms (Giske et al., 2008; Lode, 2009; de Kraker et al., 2011a; 2011b; 2011c; Pietersen et al., 2014; Pop-Vicas and Opal, 2014).

Invasive infections with methicillin-resistant *Staphylococcus aureus* (MRSA) have frequently been shown to be associated with a higher mortality and an increase in hospital length of stay when compared to methicillin susceptible *Staphylococcus aureus* (MSSA) (Lode, 2009; de Kraker et al., 2011a; 2011b). Similar associations are found when looking at enterococci. Vancomycin-resistant enterococci (VRE) bloodstream infections are associated with a higher mortality than vancomycin susceptible enterococci bloodstream infections (Lode, 2009). Although prior studies had not shown a higher mortality with penicillin-resistant pneumococcal infections (Moroney et al., 2001; Lode, 2009), a more recent meta-analysis has shown penicillin-resistant pneumococcal infections to be associated with a higher mortality compared to penicillin-susceptible infections (Tleyjeh et al., 2006; Lode, 2009). Similar outcomes have been noted for antibiotic-resistant gram-negative infections. *Escherichia coli* and *Klebsiella pneumoniae* strains resistant to extended-spectrum cephalosporins, multidrug-resistant (MDR) *Pseudomonas aeruginosa* strains, and carbapenem-resistant *Acinetobacter* infections have all been associated with an increased length of stay and mortality when compared to their more susceptible counterparts (Giske et al., 2008; de Kraker et al., 2011a; de Kraker et al., 2011c; Lemos et al., 2013). Specifically, this mortality is noted to be higher when study antibiotic-resistant gram negative bacilli in the setting of septic shock (Pop Vicas and Opal, 2014). One plausible reason for this finding is the difficulty in selecting an appropriate empiric antibiotic regimen in the era of highly drug-resistant gram-negative infections. It is well established that the duration of hypotension without appropriate antimicrobial therapy is a crucial factor in the probability of survival in septic shock (Kumar et al., 2006). In addition to gram-positive and gram-negative pathogens, drug-resistant tuberculosis has also been shown to have a higher mortality compared to drug-susceptible tuberculosis (Pietersen et al., 2014).

For all different types of drug-resistant infections, an increase in mortality affects more than just the patient when examined using the public health perspective. Although difficult to quantify, the consequences of premature death include a loss of productivity (number of productive years lost multiplied by the average yearly productivity) and the pain and suffering of family members and friends (Laxminarayan and Malani, 2007).

EVOLUTION OF RESISTANCE

Antimicrobial resistance is a global dilemma that threatens the health and safety of populations in all countries of the world. Urgent actions are needed to be taken before it reaches a critical stage, when large numbers of people in communities cannot be treated for life-threatening infections due to lack of effective drugs. Although the threat is most imminent from antibacterial resistance to commonly used antibiotics for infections seen regularly in intensive care units and hospitals, it is more prevalent and widespread and involves a wide spectrum of microbes.

To understand the evolution of microbial resistance, it is appropriate to review historical aspects. Development of antimicrobial chemotherapy is usually attributed to Paul Ehrlich ["father of chemotherapy"] based on his quest to find a cure for parasitic infections, toward the latter part of the nineteenth century, with natural dyes and heavy metals [mercury and arsenicals]. Penicillin was subsequently discovered in 1928 and administered clinically in the

1940s; sulphonamides were introduced clinically in 1937 (Greenwood et al., 2007). Thus, the “antibiotic era” was under way by the early 1940s. Penicillin and other antibiotics were initially derived from environmental fungi and bacteria, often with improvements made by chemical synthesis. Hence, the origin of antibiotics is through naturally derived substances produced to antagonize or inhibit the growth of other microorganisms, probably due to an evolutionary process that protects environmental niches of the producing organisms.

Streptomycin and the precursor of cephalosporins were also obtained from soil microbes in the 1940s. Penicillin was first used in 1941, and by 1944 penicillinase producing *Staphylococcus aureus* was described. Streptomycin was introduced clinically in 1944 for treatment of tuberculosis, but resistance soon developed during treatment (Davies and Davies, 2010). By the mid-1950s, most of the major antibiotic families, including aminoglycosides, chloramphenicol, tetracycline, and macrolides, had been developed (Greenwood et al., 2007).

Synthetic chemical agents with antibacterial activity were introduced in the early 1950s with para-aminosalicylic acid and isoniazid as antituberculosis agents; nitrofurantoin was found around the same time, followed by trimethoprim in 1956. Nalidixic acid, discovered in the early 1960s, was the precursor of the fluoroquinolones, with norfloxacin and ciprofloxacin developed in the 1980s. Rifampin was introduced for tuberculosis in 1968. The spectacular success of antimicrobial therapy led to widespread use and emergence of resistance. Pharmaceutical companies saw profit in new, more potent derivatives, which gave rise to broad-spectrum antipseudomonal penicillins and second-generation cephalosporins in the 1970s, with subsequent introduction in the 1980s of third generation cephalosporins. Later, beta-lactamase inhibitors combined with broad spectrum penicillins and carbapenems, new glycopeptides, newer macrolides, later generation quinolones, linezolid [a new class of oxazolidinone], and glycylcyclines [tigecycline] were introduced. Currently, there are more than 100 antimicrobial compounds available.

It is important to understand the evolution of antimicrobial resistance in order to tackle the problem. It was initially thought that antimicrobial resistance was a modern, man-made phenomenon. Although penicillinase-producing bacteria were recognized soon after the discovery of penicillin, it was not recognized as a problem until clinical use of penicillin became widespread. By the end of the 1950s, 80% of *Staphylococcus aureus* isolated from hospital patients were penicillin resistant due to β -lactamase production (Greenwood et al., 2007). This observation led to the development of penicillinase-stable penicillins [methicillin, cloxacillin, and oxacillin] which were introduced in the early 1960s to treat *S. aureus*. But resistance to methicillin was seen within a year or so of its clinical introduction. Thus, this was a sign that microbial resistance would be a problem, but in most cases this was overcome with development of new, more potent compounds. Many agents were developed that initially failed to compete well in the marketplace. The lack of use kept resistance from emerging, and now they are being used more frequently to fill a niche. Vancomycin is one of these agents. It was approved for use in 1958, but it was used sparingly due to concerns of toxicity and efficacy.

When methicillin-resistant *S. aureus* [MRSA] appeared in hospitals during the 1970s and then spread to other health-care facilities, vancomycin became more frequently used, beginning in the 1980s (Levine, 2006). Similarly, polymyxins were developed in the 1950s, but toxicity kept them from widespread use for systemic infections. Now they are gaining clinical use with infections caused by *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, and carbapenemase-producing *Enterobacteria-ceae* that are resistant to all other antibiotics

(Landman et al., 2008). Full vancomycin resistance among MRSA strains is rare, probably because mutational changes cause impaired fitness for MRSA as susceptibility decreases. As a result, vancomycin-intermediate resistance [VISA] is slowly becoming a problem. Resistance to polymyxins appears to be emerging readily with increased use.

Over the years, development of new antibiotics to counter resistant bacteria led to appearance of novel resistant strains to these new drugs, which become widespread with increasing use of the antibiotics. This pattern has been seen with every new class of antibiotic developed over the years. There is strong correlation between the frequency and quantity of antibiotics used in humans and animals and the rate of development of antibacterial drug resistance. The logarithmic growth of resistant bacteria since the 1970s is reflected by the number of β -lactamase enzymes identified during the antibiotic era. Before 1970, there were only several β -lactamase enzymes described, and now about 900 β -lactamase enzymes have been identified (Davies and Davies, 2010).

Mobile genetic elements, extra chromosomal self-replicating structures [plasmids] and transposons, found in bacterial cells provide a resistance threat that maybe unconquerable. Our understanding of horizontal transfer of bacterial resistance was heralded by the discovery of antibiotic resistance plasmids that could be disseminated by bacterial conjugation in the mid-1950s (Davies and Davies, 2010). Since 1989 we have gained much greater knowledge of the genetics of bacterial resistance following the discovery of integrons. Integrons are versatile genetic elements, commonly found in bacterial genomes that allow efficient capture and expression of exogenous genes.

Plasmids and transposons are considered mobile integrons. Integrons play a major role in the spread of antibiotic resistance, particularly in Gram-negative pathogens; the majority of these pathogens carry integrons with resistant genes (Gillings, 2014). The process of microbial resistance is complex, and besides plasmids and DNA mutations [acquired or heritable and transferable], other mechanisms include biofilms, which harbor hypermutator bacteria that select for resistance more frequently, and phenotypic tolerance, a situation in which bacteria are not killed by antimicrobials (Nathon, 2012). Antibiotic pressure predisposes to resistance and tolerance. Despite the call for intensive research on mechanisms of microbial resistance and development of novel compounds to counteract the spread in 2012 (Nathon, 2012), no innovative agent is on the horizon.

Figure 1. Appearance of antimicrobial resistance. Abbreviations: MRSA methicillin-resistant *S. aureus*, VRE vancomycin-resistant enterococci, ESBL extended β -lactamase.

The origins, evolution, genetics, and biochemistry of antibiotic resistance have been studied over the last 60 years. Figure 1 outlines the history of antibiotic discovery and subsequent development of antibiotic resistance. The emergence of antibiotic resistance of pathogenic bacteria after antibiotic development and clinical use, plus the absence of resistance in bacteria of the pre-antibiotic era (Hughes and Datta, 1983), suggested that resistance is a modern phenomenon. However, metagenomic analyses of authenticated ancient DNA from 30,000-year-old Beringian permafrost sediments identified genes encoding resistance to β -lactam, tetracycline, and glycopeptides antibiotics (D'Costa et al., 2011). Thus, antibiotic resistance is a natural phenomenon that predates the modern selective pressure associated with clinical and animal use. This explains the rapid emergence of resistance to new antibiotics; resistance will continue to emerge with drugs now in development. Hence, it is predictable that new antibiotics will select for preexistent resistance determinants that have been present and circulating in universal, environmental microbial pangenome for hundreds of years (D'Costa et al., 2011). Thus, the era of antibiotics has shifted naturally to the era of antibiotic resistance. The main challenge is to minimize the problem.

CONCLUSION

Human migration, animal and vector movement, and food markets may facilitate the spread of antimicrobial resistance across almost any geographic or political boundary. Methicillin-resistant *Staphylococcus aureus* and vancomycin resistant *Enterococcus* were first reported in the United Kingdom. After becoming widespread in North America and Europe, the same resistance patterns were noted in Asia. Today, novel gram-negative carbapenem resistance mechanisms such as OXA-48 and NDM-1 (New Delhi metallo- β -lactamase) were first discovered in Asia and have since spread to Europe and North America. The global spread of antimicrobial resistance demands effort of multiple health and industry sectors (in both low-resource and high-resource countries) to strengthen multinational/international partnerships and regulations. Public health must be at the forefront of these efforts.

Chapter 535

STRATEGIC FACILITIES MANAGEMENT APPROACH IN AUSTRALIAN PUBLIC HEALTHCARE ORGANISATION

Yuhainis Abdul Talib*, Nor Aini Salleh and Kharizam Ismail

Faculty of Architecture, Planning and Surveying, Universiti Teknologi
MARARA Perak Branch Seri Iskandar Campus, Seri Iskandar, Perak, Malaysia

ABSTRACT

The objective of this paper is to identify the relationship between Facilities Management Business Operation and facilities management support services delivery (FMssd). A public healthcare organisation in regional Victoria was used as a case study. A quantitative method approach is used with strategies for inquiry that multiples regression technique. The questionnaires were distributed to clinical and non-clinical staffs in the organisation. Three dimensions of healthcare management were evaluated in clusters of variables: business organisation management, facilities management operation system and decision making process. The data was analysed using a statistical tool (SPSS 20). The method used is a standard multiple regression. The healthcare management has to understand the nature of every FMssd item better. This paper has found a strong idea and understanding of the link between operational management and organisational management in order to understand how to effectively manage healthcare buildings facilities better.

Keywords: facilities management, hospital, decision making

INTRODUCTION

In order to ensure facilities management (FM) is strategically managed, the public healthcare management needs to understand a different concept of managing various kinds of buildings. FM theory in organisations lie in three elements, namely process, place and people

* Corresponding Author's Email: anis500@uitm.edu.my.

[1]. Firstly, process in FM strategic management is business operations. It is a support service to the core business operation of the organisation. Secondly, the building is the place where the core business runs by FM service delivery support. Thirdly, the building users are people. The objective of this paper is to identify the significant relationship between FM support service delivery (FMssd) and facilities business operation (FBO) for Public Hospital in Australia.

The implementation of strategic facilities management seems to lack in terms of promoting the aspects of integration and holistic approach. Therefore, in the early stages of the FM era, financial indicators were the business' only performance measure [2]. FM is approached in many ways, making it difficult to bridge knowledge and thus creating a coherent body of FM knowledge [3].

How can FM processes be innovative with business strategic management? FM is not about reducing running costs of building or maintaining costs but the business as a whole. Performance measurement is a vital tool; as a means of balancing multiple measures across multiple levels [5]. TQM is one of the most established tools, but an integrated tool is still yet to be explored [4]. Tucker and Pitt [2] trust that the scarcity of a FM holistic approach in business solutions may cause an ineffective application of strategic facilities management.

Mohd Noor and Pitt [6] considered that in order to establish FM organization into business strategic, FM management teams need to provide adequate resources, ample working space and practical guidelines to the operational FM system. However, some healthcare organisations, especially private healthcare may not be able to cope or provide sufficient resources and expertise in FM operation.

STRATEGIC FACILITIES MANAGEMENT APPROACH

Enhancing the decision-making process of HFMs will not only prevent the devastating consequences of error in this area, but will also increase the productivity of the facility and sustainability of the healthcare infrastructure [7].

FM discipline is infancy knowledge-based from the businesses corporate perspective [6]. FM is meant to allocate core business physical resources in a way that allows it to flourish in competitive and dynamic markets. Despite the robust definitions, it is the client's responsibility to ensure how FM can operate in a diligent manner. The client's decision-making has to align with the FM strategic operation in order to gain effectiveness in service delivery. FM is capable of carrying out the strategic role if the FM division has a distinctive knowledge-based on how to source and evaluate between "intra-firm" administrative governance and "inter-firm" contractual arrangements [8].

FM Support Service Delivery

Clients and service providers have indicated that applying the FM outsourcing relationship types improves the quality of the services. Meanwhile, the results from the past literature has found that FM outsourcing relationship types are used in related services; that is, the outsourcing categories of a specific FM outsourcing contract will be achieved through

prediction at the level of substitution of ownership, substitution of control, competitive positions and long term planning [9].

FM support services exist from the user's requirement and the organisation's nature of business [10]. The author claims that the term "support service within FM" needs to be clearly defined. Traditionally, FM support service is understood to be one of the support system to core activities of an organisation. Hence, it can be argued for strategic reasons that support and core are the same, for operational purposes that clarifies services between support and core is best confined within one organisation [10].

Healthcare Strategic FM Efficiency

FM must take certain management challenges that go beyond the current perspective of FM being a mainly engineering- and cost-driven discipline that deals with the built environment into account [11]. Implementation of FM in business strategy creates a substantial holistic culture, and strategy through quality of service [6]. On the other hand, Rogers [12] believes that differences in operational effectiveness between organisations are pervasive.

Business Organization Management

Outsourcing is one of the most effective ways to ensure that healthcare business management can operate without worrying about the non-core support system, which is complicated and requires specialised and highly technical skills. However, outsourcing is not a favourite option to most public healthcare organisations. It is more suitable for private healthcare organisations that are profit-oriented, where there are no compromises on the core or non-core healthcare services. Furthermore, the demands of private healthcare organisations are high and require expertise in order to generate business. Undoubtedly, FM when integrated with business strategies gives a more modern image; reduces unnecessary costs and enhances the working environment [6].

Strategic FM looks into business performance to achieve business objectives. Nevertheless, before they can be achieved, the FM operation has to understand how the buildings perform or behave. Past literatures have discussed FM performance, but less literature is available on building performance itself, or relating both strategic FM service delivery and building performance [13 - 15].

FM Operation System

FM has become very conventional in its approach and purpose. In a business context, FM has played a significant role in strategic decision making to enhance core function of the business. To develop a business function, Atkin and Brooks [21] highlight three stages: (i), analysis stage is to incorporate business objectives, needs and policies, review of resources, processes, system and the physical assets in terms of space, function and

utilisation. (ii), solution stage, which it involves judging options, evaluating the organisation's objectives and developing the FM strategy, and (iii), implementation stage completes the strategy development process through the establishment of an implementation plan through procurement, training and communication. The author then ensures that, upon completion, the FM strategy should form part of the organisation's strategic and operating plan.

Decision Making Process

Study revealed that the need to have a strategic focus on organisation's core goals is the most influential factor for outsourcing FM services, while the need to instil cost transparency and to improve the satisfaction of customers were among the highly rated factors, thus providing a framework for decision-making within organisations [22].

Boussabaine and Kirkham [23] implement the Data Envelopment Analysis (DEA) methodology to examine the organisational management aspect of PM. The efficiency of PM techniques used by the National Health Service (NHS) in United Kingdom was taken as a case study. The study has found that it is important for estate managers to select input variables that demonstrate large effects of inefficiencies in management because organisational changes and decisions for efficiency improvements are costly to implement. Although more comprehensive approaches to linking FM costs are needed in terms of inpatient days or other appropriate output variables, findings from this analysis has proven to be valuable for improving the managerial decision making process. To show more significant contributions into strategic management [24], integrate two domains in Performance Indicators (PIs) namely organisational and operational. The results found that the disconnection between two domains, as well as vast levels of stakeholders, cause absentee in facility maintenance strategic decision making.

METHODOLOGY

To answer the research objective of this paper, quantitative method is used to analyse an agreement levels on business organisation management (BOM), facilities management operation system (FMOS) and decision making process (DMP). Information was gathered from preliminary interviews, a literature review, and BREEAM toolkit (AEDET) and the data was used for subsequent surveys. Adapted from UK NHS Toolkit, AEDET Toolkit Evolution is an assessment to provide comprehensive evaluation of the design of healthcare.

The survey questionnaire is mainly quantitative that comprises of Part 1- Facilities Management Support Services Delivery (FMssd) and Part 2 - Facilities Business Operation (FBO). 360 respondents are from clinical staffs and non-clinical staffs. Completed questionnaires were managed in two ways. For the paper survey, questionnaire surveys were individually coded and filed. Both surveys were entered into the computer database using statistics software called Statistical Package for the Social Science (SPSS Version 20). Based on a large sample size and nature of data (interval level scaling), this study applied a parametric statistics technique. The decision of using parametric technique is based on a few

factors, namely level of measurement, random sampling, and independence of observations, distribution and homogeneity of variance [25].

To ensure this study can use parametric statistics technique, the following steps were taken beforehand [25].

- i. Checking the distribution of scores on all independent and dependent continuous variables
- ii. Test of normality: represented by Kolmogorov-Smirnov statistic.
- iii. Checking for outliers: Outliers can be checked by examining the histogram and boxplot.
- iv. Scatterplots: Scatterplots is used to explore the relationship between continuous variables.

To achieve the result, the parametric technique called the multiple regressions was used. The screening and cleaning data were completed at the early stages before proceeding to statistical analysis to ensure that there are no missing data and, if there were any, the data was rectified.

Standard multiple regression techniques were chosen to explore the relationship between one dependent variable against 3 independent variables (FMssd), which was divided into three constructs; FMcs, FMfs and FMn-cs against predicted outcome (dependent) variable, namely FBO's three factors; (i) business organisation management (BOM), (ii) FM operation system (FMos), and (iii) decision making system (DMS).

Regression analyses are a set of statistic techniques that allow one to access the relationship between one dependent variable and several independent variables [26]. Multiple regressions are selected to predict an outcome variable from several predictor variables. Standard multiple regressions used the following mathematical equation to identify the relationship:

$$\begin{aligned} y &= \text{dependent variables} \\ b_1 &= \text{regression coefficient} \\ x_1 &= \text{independent variables} \end{aligned}$$

To be more precise, considering there will be deviations between the value from Y and the value from X, where the standard regression model will not fit the data perfectly, Field (2012) proposed the equation that considers the residual (deviations) as

$$Y_i = (b_0 + b_1X_i) + \varepsilon_i \quad (1)$$

RESULTS AND DISCUSSIONS

In this study, standard multiple regressions was undertaken to describe how strong each independent variable (FMss, FMfs and FMn-cs) was when evaluated in terms of its predictive power, over and above that was offered by all the other independent variables [25]. Furthermore, this approach explained how much unique variance in the dependent variable

was explained by each of the independent variables. Standard multiple regressions were used because both predictor and dependent variables had been theory tested. The predictor (FMssd) had gone through a preliminary survey. As for dependent variables, the FBO factor with its three constructs (BOM, FMos and DMP) was mentioned in the literature review as one of the gap/issues in strategic FM.

Table 1. Multicollinearity test for FBO for “A”, a public health care organisation

DV	Predictive variables	Tolerance	VIF	Mahalanobis distance	Cook's distance
Business organisation management (BOM)	FMcs	.310	3.321		
	FMfs	.013	4.017	2.977	.008
	FMn-cs	.332	3.008		
FM operation system (FMos)	FMcs	.318	3.145		
	FMfs	.252	3.971	2.039	.018
	FMn-cs	.333	3.000		
Decision making process (DMP)	FMcs	.328	3.053		
	FMfs	.255	3.928	2.009	.025
	FMn-cs	.314	3.184		

Relationship of FMssd to FBO: The Influence of FBO Factors on FMssd for “A”, the Public Health Care Organization

Evaluating the model (FBO_FMssd)

This model is intended to evaluate the FMssd against three FBO constructs, namely: (i) business organisation management (BOM); (ii) the facilities management operation system (FMos); and (iii) the decision-making process (DMP). Evaluating the model generated from this standard multiple regression analysis has provided an idea of the percentage of variance of FMssd against the FBO factors, which can be described as FM organisational management. Adjusted R² used as this sample is considered to be a small to average size sample (119 cases to 128 cases), and indicates the regression equation of percentage variance. Adjusted R² is used to explain how much variance occurs. The model (FMssd) shows (see Table 2) that the highest percentage of variance is “BOM”, presenting 2%, the second is “DMP” which owned 1.9% and the lowest is “FMos” which contributed 1%. Furthermore, it is worth looking at the individual predictor (square from part correlation), where it was found that FMcs was making the largest contribution on all of the constructs. FMcs was found to have contributed 0.2% for BOM, 1.6% for FMos and 0.3% for DMP of variance alone. However, of all the dependent variables, none were found to be statistically significant: (i) BOM ($F(3,173) = 0.149$, $p > 0.05$), (ii) FMos ($F(3,127) = 1.418$, $p > 0.05$), and (iii) DMP ($F(3,119) = 0.256$, $p > 0.05$). Therefore, from this model, FMssd did not happen to predict all FBO constructs.

Evaluating FMss, FMfs and Fmn-cs

All three predictors predicted the FBO construct, namely; BOM, FMos and DMP. The description is as follows:

(i) Business organisation management (BOM)

FMcs ($b = 0.142$, $\beta = 0.072$, $t = 0.456$, $p > 0.05$), FMfs ($b = 0.036$, $\beta = 0.026$, $t = 0.146$, $p > 0.05$) and FMn-cs ($b = -0.156$, $\beta = -0.065$, $t = -0.426$, $p > 0.05$) did not significantly predict “business organisation management” (BOM). For FMfs and FMcs, their beta value indicated that as these constructs increased, the BOM also increased. This result showed that the more important the fundamental and core FM support services, the more efficient the BOM. As for FMn-cs, there was a negative correlation where the more important the non-core FM, the less efficient the BOM. BOM items are related to health care organisational management. Businesses operating such facilities face two choices; either they have to make the operation a core competence of its own, in which case logic dictates that it becomes their core business, or part of it, or else they should be sourcing the business critical services from a firm who has core competence in such services. This result showed that core and fundamental FM services, but not the non-core FM, promote the efficiency of health care organisational management. FM operates in a customised manner, wherein the business support service is designed and accessed according to the strategic needs of the changing business.

(ii) Facilities management operation system (FMos)

FMcs ($b = 0.343$, $\beta = 0.226$, $t = 1.461$, $p > 0.05$), FMfs ($b = 0.039$, $\beta = 0.036$, $t = 0.210$, $p > 0.05$) and FMn-cs ($b = -0.227$, $\beta = -0.124$, $t = -0.822$, $p > 0.05$) did not significantly predict “facilities management business operation” (FMos). For FMfs and FMcs, their beta value indicated that as this construct increased, the FMos also increased. This result showed that, the more important the fundamental and core FM support services, the more efficient the FMos. As for FMn-cs, there was a negative correlation, where the more important the non-core FM, the less efficient the FMos. FMos items are related to the FM system in health care. This result showed that core and fundamental FM services, but not the non-core FM, promote the efficiency of the FM system in health care. Facilities issues can critically affect investment decisions, operational efficiency and cultural attitudes, so bringing them into centre stage can create a comprehensive view of the corporate condition. Furthermore, the facilities department will be organised as a profit centre and will seek to create the relationships that will enable the service to develop, with continual improvement of quality, better value for money and at minimum risk to the organisation.

(iii) Decision-making process

FMcs ($b = 0.142$, $\beta = 0.089$, $t = 0.560$, $p > 0.05$), FMfs ($b = 0.042$, $\beta = 0.037$, $t = 0.205$, $p > 0.05$) and FMn-cs ($b = -0.116$, $\beta = -0.062$, $t = -0.381$, $p > 0.05$) did not significantly predict “decision-making process” (DMP). For FMfs and FMcs, their beta value indicates that as these constructs increased, the DMP also increased. This result showed that, the more important the fundamental and core FM support services, the more efficient the DMP. As for FMn-cs, there was a negative correlation, where the more important the non-core FM, the less efficient the DMP. DMP items are related to the decision-making process in health care organisation management. This result showed that core and fundamental FM services unlike the non-core FM services promote the efficiency of the decision-making process in health care organisational management.

As a conclusion, all FBO constructs seemed to have shown the same result, where all three constructs that resulted with their FMcs and FMfs did have a positive correlation. However, FMn-cs gained a negative correlation against all BOM, FMos and DMP. However, bear in mind that none of these results were significant.

Table 2. Standard multiple regression (FBO)

DV	Variables	Coefficients					ANOVA		Model Summary	
		B	SE	β	T	P	F	Sig.	R ²	Adjusted R ²
Business organisation management (BOM)	FMcs	.142	.312	.072*	.456	.649				
	FMfs	.036	.245	.026	.146	.884	.149	.930	.003	.020

	FMn-cs	-.227	.276	-.124	-.822	.412				
Decision-making process (DMP)	FMcs	.142	.254	.089*	.560	.576				
	FMfs	.042	.204	.037	.205	.838	.259	.855	.006	.019
	FMn-cs	-.116	.306	-.062	-.381	.704				

*Indicates largest beta coefficient

CONCLUSION

FMssd was found not to predict all three FBO constructs, namely, BOM, FMos and DMP, as well as FMssd individual constructs, FMcs, FMfs and FMn-cs. The only strong finding was that FMcs has the largest impact of all FBO constructs, namely Business organisation management (BOM), FM operation system (FMos) and Decision-making process (DMP). It can be concluded that the efficiency of FBO is not affected by the importance of any FMssd construct or FMssd as a whole.

Chapter 536

CLIMATE CHANGE: HHS COULD TAKE FURTHER STEPS TO ENHANCE UNDERSTANDING OF PUBLIC HEALTH RISKS*

United States Government Accountability Office

WHY GAO DID THIS STUDY

The World Health Organization projects climate change will adversely affect health significantly over the next several decades. Some health effects of climate change are already being felt in the United States, according to assessments by the National Research Council, USGCRP, and others. Since the federal government is the nation's largest purchaser of health care services, federal health care expenditures could increase in future years due to climate-related impacts.

GAO was asked to review federal efforts to increase public health system preparedness for climate change. This report addresses (1) federal activities to enhance understanding about the risks climate change poses to public health, (2) federal resources used by selected states and localities to address these risks, and (3) challenges states and localities face and actions federal agencies could take to mitigate them. GAO examined federal, state, and local documents, and interviewed officials from federal agencies such as CDC, NIH, USGCRP, as well as state and local health departments, including all 18 recipients of CDC's Climate Ready States and Cities Initiative award.

* This is an edited, reformatted and augmented version of the United States Government Accountability Office publication, GAO-16-122, dated October 2015.

NIH	National Institutes of Health
NOAA	National Oceanic and Atmospheric Administration
USGCRP	U.S. Global Change Research Program

WHAT GAO RECOMMENDS

GAO recommends that HHS direct CDC to develop a plan describing when it will be able to issue climate change communications guidance to state and local health departments. CDC generally agreed with the recommendation, stating that it will issue guidance once HHS's climate change communication and outreach strategy is final.

WHAT GAO FOUND

Federal agencies are enhancing understanding of climate-related risks to public health by (1) supporting and conducting research, (2) providing data and informational resources, and (3) communicating about risks. The Department of Health and Human Services' (HHS) National Institutes of Health (NIH) supports a portfolio of research directly related to these risks. NIH reports awarding about \$6 million for such research in fiscal year 2014, including for one study examining health risks posed by heat and air pollution. Federal agencies have also provided data on climate and health issues, such as the number of extreme heat days that state and local officials can use to assess health risks. They have also reported about these risks, such as through the third National Climate Assessment issued in May 2014 by the U.S. Global Change Research Program (USGCRP).

Selected state and local health departments have used resources from HHS's Centers for Disease Control and Prevention (CDC) and other federal agencies to address and plan for the risks of climate change to public health. CDC's Climate Ready States and Cities Initiative awards an average of about \$200,000 per year each to 16 state and two local health departments to implement a risk management framework designed to help incorporate climate projections into public health planning. CDC also requires awardees to increase public awareness of the risks climate change poses to public health. Other federal resources used by

health departments to prepare for these risks include funding provided through CDC's National Environmental Public Health Tracking Program.

When asked to identify challenges they face in addressing and planning for the risks of climate change to public health, state and local health officials identified challenges that GAO grouped into the three most frequently mentioned themes. First, the officials said they face challenges communicating about the public health risks of climate change, due to limited public awareness and the complexity of the issue. These officials reported that enhanced federal leadership could help address this challenge. Although HHS plans to develop a climate change communication and outreach strategy, its development has been delayed by over a year. Also, CDC currently does not have plans to issue climate change communications guidance, which state and local officials said would be helpful. CDC's limited resources are currently focused on resolving methodological and data issues related to its Climate Ready States and Cities Initiative. Given that health departments that have received awards under CDC's initiative are required to take steps to enhance public awareness, such guidance may help awardees better meet this requirement. Issuing such guidance would also be in line with CDC's core functions, which include translating climate change science to inform communities. Second, officials said they face challenges identifying health risks of climate change due to gaps in research and difficulties using climate data. Federal officials told GAO about actions they have taken or plan to take that could help address these challenges, such as issuing an assessment of climate change impacts on health, and creating a national heat health information system. Finally, the officials told GAO about other challenges they face that federal action may not be able to address, such as having insufficient local data on health outcomes, because states may not collect or have access to such data, and having insufficient staff resources for these activities.

October 5, 2015

Congressional Requesters

The effects of a changing climate are viewed as threats to human health in a variety of ways, and, according to assessments by the National Research Council, the U.S. Global Change Research Program (USGCRP), and the Intergovernmental Panel on Climate Change, some effects are already being felt across the world and within the United States.¹ The World Health Organization projects that climate change will have significant adverse effects to health over the next several decades, including an increased number of deaths in 2030 from impacts such as heat exposure, malaria, diarrhea, and childhood malnutrition.² Observations of a changing climate in the United States include trends such as an increase in average temperatures, shifting patterns of rainfall, rising sea levels, and more frequent and intense extreme weather events such as heat waves, heavy downpours, and drought, according to reports from the National Research Council and USGCRP. While it is challenging to link any individual weather event to climate change, the National Research Council and USGCRP, among others, expect these climate trends to continue. According to assessments by the National Research Council and USGCRP, climate change will amplify existing health threats, and populations such as the elderly, children, those who are sick, and those living in poverty

will face disproportionate health risks from climate change in the United States.³ In addition to being the nation's largest purchaser of health care services, the federal government bears the expense of these services for some of the most vulnerable populations to climate change impacts—spending \$815 billion on three such programs in 2014.⁴ As such, federal health care expenditures could increase in future years as a result of climate impacts. A 2006 summer heat wave in California illustrates the types of health impacts that could be associated with climate change, including increased hospitalizations for heat-related illnesses.⁵ In February 2013, we added limiting the federal government's fiscal exposure by better managing climate change risks to our High Risk List, which calls attention to agencies and program areas that are at high risk due to their vulnerabilities to fraud, waste, abuse, or are most in need of transformation.⁶

State and local public health authorities have responsibility for carrying out most public health activities in the United States, but a number of federal agencies also have a role. State and local public health agencies have responsibilities such as disease surveillance and responding to public health emergencies within their jurisdictions, including activities that may be related to climate change.⁷ The federal government's role in addressing public health includes providing high-level leadership through setting and communicating health-related policies, goals, and standards; supporting state and local health department efforts; and financing research and higher education. In addition, federal agencies, such as the Environmental Protection Agency (EPA), Department of Health and Human Services' (HHS) National Institutes of Health (NIH) and Centers for Disease Control and Prevention (CDC), and the Department of Commerce's National Oceanic and Atmospheric Administration (NOAA), support the development of data and other information resources on climate change that others, including state and local health departments, can use to manage public health risks. CDC has also provided support to some state and local health departments to manage these risks.

You asked us to review federal efforts to increase the preparedness of the nation's public health system for the impacts of climate change. In this report, we (1) discuss the types of activities that selected federal agencies have conducted to enhance understanding about the risks that climate change poses to public health; (2) describe federal resources used by selected state and local health departments to address or plan for the risks that climate change poses to public health; and (3) examine challenges, if any, identified by state and local officials to addressing or planning for the risks that climate change poses to public health, and any steps they identified that federal agencies could take to mitigate these challenges.

To describe the types of activities that federal agencies have conducted to enhance understanding about the risks that climate change poses to public health, we reviewed federal documents such as USGCRP's 2014 third National Climate Assessment (NCA) and a 2010 report on climate change and human health research needs.⁸ We interviewed officials from 26 federal agencies, including CDC, EPA, NIH, NOAA, and others participating in a USGCRP working group on climate change and human health.⁹ We also interviewed representatives of 13 stakeholder groups, including public health organizations, such as the American Public Health Association,¹⁰ and academic institutions, such as the Georgetown Climate Center.¹¹ (App. I provides a complete list of agencies and stakeholders interviewed.) In addition, we reviewed NIH data on awards it made for research related to the public health risks of climate change from fiscal year 2011 through fiscal year 2014.¹² To assess the reliability of these data, we discussed them with agency officials, reviewed them for reasonableness and consistency,

and determined that they were sufficiently reliable for our purposes. The results of our work provide examples of federal activities to enhance understanding of the risks that climate change poses to public health, and do not represent an exhaustive list of federal actions in this area.¹³ We did not evaluate the effectiveness of federal efforts to enhance understanding, as this was outside the scope of our review.

To describe federal resources used by selected state and local health departments to address or plan for the risks that climate change poses to public health, we used a variety of approaches to obtain information from state and local health departments. This included information about the activities they have conducted related to climate change and public health, and how they used federal resources to support these efforts. Specifically, we conducted interviews with state and local officials during site visits to two states—California and Maryland—and two cities—New York City and San Francisco—that received awards from CDC’s Climate Ready States and Cities Initiative, which is HHS’s primary investment in climate change adaptation.¹⁴ We selected these four locations from among the 18 awardees of CDC’s Climate Ready States and Cities Initiative to obtain geographic diversity, because climate change impacts are location-specific, and to have a mixture of state and local governments, because states and municipalities may have different approaches in preparing for the public health risks of climate change. We also facilitated four small group discussion sessions with officials from 22 state and local health departments to gather additional information about federal resources used by state and local health officials. We worked with representatives of the Association of State and Territorial Health Officials (ASTHO)¹⁵ and the National Association of County and City Health Officials (NACCHO)¹⁶ to identify state and local public health officials who have expressed interest in climate change issues to participate in these sessions.¹⁷ In a third approach to gather perspectives, we interviewed officials from a nongeneralizable sample of 11 state and local health departments that reflected geographic diversity and that had either recently faced climate-related public health issues, had conducted work to plan for potential future health impacts from climate change, or had concerns about potential future health impacts. In total, through these approaches, we interviewed officials from all 18 state and local health departments that received awards from CDC’s Climate Ready States and Cities Initiative, officials from 7 local health departments in some of those jurisdictions, and health department officials from 13 other states and localities.¹⁸ These interviews and small group discussions included open-ended questions that were not conducive to quantitative analysis. Therefore, using a qualitative approach, we identified examples of the types of federal resources that these officials have used to address and plan for the risks that climate change poses to human health. We also reviewed Climate Ready States and Cities Initiative awardees’ annual progress reports to CDC. To obtain more information about these resources, we reviewed documentation about the types of support they offered, such as from funding opportunity announcements. We also reviewed information on fiscal year 2014 funding for CDC programs cited by state and local officials, as presented in the agency’s congressional budget justification for fiscal year 2016. Furthermore, we interviewed officials from federal agencies, such as CDC and NOAA, and gathered the perspectives of stakeholders through interviews with representatives from groups such as ASTHO and NACCHO. The results of our review do not provide an exhaustive list of federal resources that state and local health departments could use to address and plan for the public health impacts of climate change, but are provided as illustrative examples of such resources.

To examine challenges identified by state and local officials to addressing or planning for the risks that climate change poses to public health, and any steps federal agencies could take to mitigate these challenges, we gathered the views of state and local health department officials during site visits, small group discussion sessions, and individual interviews. Through an inductive analysis of officials' views, we qualitatively grouped them into three themes that were most frequently mentioned about the types of challenges these public health departments face, and, in some cases, the opportunities officials see for federal action to address these challenges.¹⁹ We also gathered the perspectives of stakeholder groups through interviews with representatives from ASTHO, NACCHO, and the Council of State and Territorial Epidemiologists. To gather information about steps federal agencies could take to mitigate these challenges, we interviewed officials from federal agencies such as CDC, NIH, and NOAA, as well as representatives from stakeholder groups. We examined federal documents, including those describing ongoing and planned federal actions aimed at reducing the impact of climate change on public health. We reviewed prior GAO work on the federal role in addressing challenges related to climate change, including challenges faced by state and local officials.

We conducted this performance audit from June 2014 to September 2015 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

BACKGROUND

Climate changes, including rising temperatures and shifting patterns of rainfall, are expected to impact public health across the nation in a variety of ways. Though state and local governments have primary responsibility for protecting the public health in their jurisdictions, the federal government also plays an important role in supporting state and local efforts by, for example, providing health departments with technical support and other resources. The federal government has also taken other targeted actions to help prepare the nation for climate change impacts, such as by issuing a number of orders, actions, and plans to provide state and local decision makers with information they need to manage such impacts, including impacts to public health.

Climate Change Impacts in the United States

Impacts from climate change in the United States have been observed, are projected to continue, and are likely to accelerate over the next several decades, with impacts varying considerably by region, according to assessments by the National Research Council and USGCRP.²⁰ According to USGCRP's third NCA, observed impacts in the United States include increases in average temperatures and precipitation, as well as changes to precipitation extremes, with variation across regions (see table 1). These and other climate

changes are projected to continue over this century and beyond, according to USGCRP's third NCA. The magnitude of climate change beyond the next few decades depends primarily on the amount of heat-trapping gasses emitted globally, and how sensitive the Earth's climate is to those emissions, according to USGCRP's third NCA.²¹

Table 1. Observed and projected impacts of climate change in the United States

	Observed and projected impacts
Temperature	• Observed impact: The last decade was the warmest on record for the contiguous United States, with 2012 as the warmest year on record.^a The average temperature has risen by 1.3 to 1.9 degrees Fahrenheit since record keeping began in 1895, with most of this increase occurring since 1970. • Projected impact: Temperature increases are projected for all regions of the country during this century, with projected increases of 2 to 4 degrees Fahrenheit in the next few decades in most areas.
Precipitation	• Observed impact: Precipitation has increased by an average of about 5 percent since 1900, with variation across regions. Heavy downpours have been increasing nationally in recent decades, with the largest increases in the Midwest and Northeast. • Projected impact: More winter and spring precipitation is projected for the northern United States, and less for the Southwest, during this century. Increases in the frequency and intensity of extreme precipitation events are projected for all regions.
Sea levels	• Observed impact: Global sea level has risen by about 8 inches over the last century. • Projected impact: Global sea level is projected to rise another 1 to 4 feet by 2100, with additional increases well beyond this century.
Extreme weather events and impacts from storms	• Observed impact: Some types of extreme weather events—such as heat waves and regional droughts—have become more frequent and intense in recent decades. • Projected impact: Droughts in the Southwest and heat waves everywhere are projected to become more intense. Rainfall from storms such as hurricanes is expected to increase, and sea level rise is expected to magnify the adverse impact of storm surges on some coastal communities.

^a The National Oceanic and Atmospheric Administration and the National Aeronautics and Space Administration have since declared 2014 as the warmest year on record since 1880.

WHAT IS A VECTOR-BORNE DISEASE?

Vector-borne diseases are transmitted by mosquitoes, ticks, and fleas. West Nile virus is one type of vector-borne disease and is most commonly transmitted to people by the bite of infected mosquitoes. First detected in North America in 1999, it has since spread to all states except Alaska and Hawaii, with outbreaks occurring every summer. Most people who are infected with West Nile virus experience no symptoms, but one in five infected people will develop a fever with other symptoms such as headaches and body aches, and a very small number of infected people—less than 1 percent—will develop a severe neurological illness that can result in paralysis or death. People who work or play outside are especially vulnerable because of greater exposures to mosquitoes.

Source: Centers for Disease Control and Prevention/James Gathany. | GAO-16-122.

Climate Change and Human Health

According to USGCRP’s third NCA, climate change is expected to impact human health in the United States by exacerbating some existing health threats and by posing new risks. For example, projected changes in temperature are expected to increase the length of pollen seasons, which could increase allergies and asthma episodes. According to USGCRP’s third NCA, extreme weather events, which are expected to become more common with climate change, are linked with increases in injuries, deaths, and mental health problems, such as anxiety and posttraumatic stress disorder. Furthermore, according to this assessment, changes in the climate may contribute to the spread of vector-borne diseases that are transmitted to humans by animals, including invertebrate animals such as mosquitoes and ticks. Examples of vector-borne diseases that currently pose health risks in some regions of North America include chikungunya virus, dengue, Lyme disease, Rocky Mountain spotted fever, and West Nile virus.²² Table 2 summarizes these and additional risks that climate change poses to human health.

WHY ARE CHILDREN ESPECIALLY VULNERABLE TO SOME HEALTH RISKS FROM CLIMATE CHANGE?

Children are more vulnerable than adults to some health risks from environmental hazards— including hazards exacerbated by climate change—because of differences in their biology and behavior. Children breathe more air relative to their body mass than adults do and their natural defenses are less developed, which makes them especially vulnerable to health impacts from decreased air quality. Asthma is one of the most common serious chronic diseases among children, and can be aggravated by poor air quality. Children also behave differently from adults, such as by spending more time outdoors and playing closer to the ground, which makes them especially vulnerable to mosquito and tick bites that can cause disease.

Source: Environmental Protection Agency. | GAO-16-122.

The type and severity of health impacts that communities and individuals face from climate change will depend on a variety of factors, and not everyone is equally at risk, according to assessments by the National Research Council, USGCRP, and others. Populations of special concern include children, the elderly, those who are sick, those who are living in poverty, those who work outdoors, some communities of color, and Native American communities.²³ According to the National Research Council and USGCRP’s third NCA, key factors in determining health risks include the following:

- **Location.** Because climate change impacts are expected to vary across the country, people will face different risks depending on where they live, work, and travel. People located in cities may be at increased risk for heat-related illnesses (e.g., heat

stroke or heat-sensitive conditions such as cardiovascular disease), for example, because land cover changes associated with urbanization, including increases in the amount of paved areas, can result in higher air temperatures compared to the surrounding rural areas, according to USGCRP's third NCA. Those who work outdoors, such as farmers, fishermen, firefighters, and utility workers, may be adversely affected by climate impacts because they have more frequent, intense, and longer exposures to the climate than the general public, according to CDC's website. For example, as extreme weather events such as floods become more frequent and severe, outdoor workers could be at increased risk of traumatic injury. Figure 1 provides examples of potential impacts by region.

Table 2. Examples of health risks posed by climate change in the United States

Health risk	Exposure or event posing health risk	Reason for increased risk from climate change
Allergies, asthma, and other adverse respiratory impacts	Pollen, smoke from wildfires, and ground-level ozone (a key component of smog)	Pollen seasons are becoming longer because of climatic changes, such as increases in the number of frost-free days. Wildfires are projected to increase in some regions in part because of drought and other stressors exacerbated by climate change. Rising temperatures can also lead to higher levels of ozone pollution.
Food-borne and water-borne illnesses	Pathogens such as disease-causing bacteria, viruses, and parasites from untreated water or other sources	Factors that contribute to flooding, such as more extreme downpours, sea level rise, storm surges, and more rapid spring snowmelt may increase releases of sewage to surface waters. In addition, diarrheal diseases caused by pathogens such as Salmonella are more common when temperatures are high.
Heat-related illnesses and deaths ^a	Unusually high temperatures, including prolonged heat waves	Extreme heat events are expected to become more frequent and intense in coming decades because of climate change.
Injuries and deaths	Extreme weather events—such as winter storms and heavy precipitation—and their aftermaths, and changes to natural or built environments that introduce hazards	Some types of extreme weather events are expected to become more frequent and severe because of climate change. Extreme weather events may result in direct injury and impact natural or built environments in ways that increase risk of injury. Heavy precipitation events may result in flash floods, which can lead to drownings.
Mental health and stress-related disorders	Any adverse change to an individual's environment, way of life, or health, such as displacement following a disaster	Climate-related disasters such as floods, heat waves, and wildfires may result in increases in mental health problems, such as anxiety and post-traumatic stress disorder.
Vector-borne diseases	Pathogens spread by vectors—including fleas, ticks, and mosquitoes—cause diseases such as dengue, Lyme disease, Rocky Mountain spotted fever, and West Nile virus	Habitats of some pathogen-carrying vectors may expand into previously unaffected regions, in part because of climate change.

Source: U.S. Global Change Research Program's third National Climate Assessment. | GAO-16-122.

^a Heat-related illnesses and deaths may result from heat stroke or heat-sensitive conditions such as cardiovascular disease, kidney disease, cerebrovascular disease, and other conditions exacerbated by exposure to extreme heat.

- **Age.** A person's age also plays a role in determining his or her vulnerability to health impacts, including those related to climate change, according to USGCRP's third NCA. For example, children suffer disproportionately from the effects of heat waves and other environmental hazards associated with climate change, according to USGCRP's third NCA. One reason is that children playing outside during heat waves

may not be aware that they need to drink more water as a preventative measure, according to EPA.²⁴ Older adults are also vulnerable to some climate-related impacts, according to USGCRP's third NCA. Specifically, this assessment states that limited mobility among older adults can increase their flood-related health risks, and that older people are at much higher risk of dying during extreme heat events.

- **Adaptive capacity.** The extent to which people and communities have the capacity to successfully adapt to adverse events also affects the health risks they face, and is influenced by characteristics such as disabilities and socioeconomic status. For example, according to USGCRP's third NCA, limited economic resources for adapting to or escaping from health-sensitive situations will place the poor at higher risk of health impacts from climate change than higher-income groups. In contrast, communities that have access to early warning systems, such as for forecasting and alerting people about impending heavy precipitation events and flooding, may be better positioned to reduce health risks from such adverse events.

Roles and Responsibilities for Managing Public Health Risks in the United States

State, local, territorial, and tribal governments have primary responsibility for managing public health risks within their jurisdiction. Public health departments vary greatly in their size, responsibilities, and resource levels, among other factors.²⁵ Activities that public health departments may undertake to help promote health and well-being include monitoring and investigating health problems, educating people about health issues, developing plans to support health efforts, and researching new solutions to health problems, among other activities.

The federal government's role in managing public health includes providing leadership through setting and communicating health-related policies, goals, and standards. Federal agencies also finance research and higher education, support state and local health department efforts, and support the development of data and decision support resources that decision makers can use to manage for risks to public health, including from climate change.²⁶ For example, through its various programs, CDC provides technical and financial support to state and local health departments to enhance their capacity to monitor and promote public health, including preparing for the risks posed by climate change. The agency's Climate and Health Program, established in 2009, supports state and local health department efforts to plan for and address the health risks posed by climate change. According to CDC, the program's three core functions are to translate climate change science into health policy for action by health departments and communities, create decision support resources to build capacity, and serve as a credible leader in planning for the public health impacts of climate change.

Federal Efforts to Enhance Resilience to Climate Change Impacts

The federal government has undertaken a number of efforts to enhance the nation's resilience to climate change impacts, such as strengthening federal agencies' adaptation

planning and providing states and localities with information for managing risks posed by climate change. In July 2014, we reported that investing in resilience—actions to reduce potential future losses rather than waiting for an event to occur and paying for recovery afterward—can reduce the potential impacts of climate-related events.²⁷ To facilitate federal efforts, the federal government has issued the following orders, actions, and plans:

- **Executive Order 13514.** On October 5, 2009, the President issued an executive order calling for federal agencies to participate in the existing interagency Climate Change Adaptation Task Force.²⁸ Based on the task force's recommendations, the Council on Environmental Quality within the Executive Office of the President issued implementing instructions for the executive order,²⁹ directing federal agencies to establish agency climate change adaptation policies, among other things.³⁰
- **The President's Climate Action Plan.** In June 2013, the White House published a climate action plan detailing actions that federal agencies would take to prepare the nation for the impacts of climate change, among other goals.³¹
- **Executive Order 13653.** On November 1, 2013, the President issued an executive order to help prepare the nation for the impacts of climate change.³² Among other things, the order called on certain federal agencies to provide information, data, and decision-support tools on climate preparedness and resilience in support of federal, regional, state, local, tribal, and other efforts to prepare for the impacts of climate change. It also established a State, Local, and Tribal Leaders Task Force on Climate Preparedness and Resilience to inform federal efforts to support climate preparedness and resilience.³³
- **April 2015 Administrative Actions.** On April 7, 2015, the White House announced a series of actions that the administration was taking to better understand, communicate, and address the health impacts of climate change, as well as commitments made by private sector entities and institutes of higher learning to further our knowledge in this area. Among other things, the administration expanded the resources available for analyzing the climate change impacts on health. (App. II provides a summary of these actions.)
- **June 2015 Climate and Health Summit and Administrative Actions.** On June 18, 2015, the White House hosted a summit on climate change and health, which included the participation of the President, the Surgeon General, and the HHS Assistant Secretary for Preparedness and Response.³⁴ At the summit, the administration announced a set of actions to protect communities from the health impacts of climate change that cannot be avoided. (App. III provides a summary of these actions.)

In addition, USGCRP has undertaken efforts to support scientific research with the goal of improving understanding of and response to climate change and its impacts on the United States. To help address climate change impacts on human health, USGCRP coordinates an Interagency Crosscutting Group on Climate Change and Human Health (CCHHG); officials from CDC, NIH, and NOAA chair this group. The mission of CCHHG is to promote and protect the nation's public health by leading and coordinating federal scientific activities related to climate change and human health, from basic research through public health

practice. CCHHG's activities include working to address key gaps in understanding of the health-related impacts of climate change and developing informational resources.³⁵

Sources: GAO analysis of U.S. Global Change Research Program's third National Climate Assessment Map Resource (map). | GAO-16-122

Note: Impacts described for certain regions do not imply that they do or can occur only in those regions.

Figure 1. Examples of potential health impacts from climate change in the United States, by region.

FEDERAL AGENCIES HAVE UNDERTAKEN VARIOUS ACTIVITIES TO ENHANCE UNDERSTANDING OF CLIMATE CHANGE RISKS TO PUBLIC HEALTH

Federal agencies have undertaken activities to enhance understanding about the risks that climate change poses to public health, including supporting and conducting research on or related to these risks. Agencies have also provided some data and decision support resources, such as guidance and tools, for state and local officials and others to use in examining public health-related risks from climate change and potential actions to address these risks. Agencies have also communicated about such risks through reporting and outreach efforts to public health officials and the general public.

Supporting and Conducting Research on or Related to the Risks Climate Change Poses to Public Health

To enhance understanding of the risks that climate change poses to public health, many of the federal agencies included in our review have supported and conducted research on or related to these risks. While governmentwide data on funding for such research is not available, NIH, which awards financial assistance for research, reports that it awarded about \$6 million to support research on the health impacts of climate change in fiscal year 2014.³⁶ This amount comprised a relatively small portion—about 0.025 percent—of the approximately \$24 billion that NIH awarded for research that year. Some of this research originated from an NIH funding opportunity—a solicitation for exploratory research projects on the health impacts of climate change—through which the agency awarded a total of about \$8.3 million for research from fiscal year 2011 through fiscal year 2014 for 21 projects. One of these projects, for example, examined the relationship between climate change and pediatric asthma.³⁷ NIH officials told us that the agency has not issued additional funding opportunities for research on climate change. These officials said that they hoped researchers who received awards from this opportunity would be better positioned to submit proposals in the future through NIH's most common submission process, in which researchers submit unsolicited proposals based on the program interests of one or more of the agency's institutes or centers.³⁸

In addition to NIH, other federal agencies, such as the National Aeronautics and Space Administration (NASA), have also conducted or supported research on or related to the risks that climate change poses to public health, including by making awards for relevant research projects and providing financial support for research teams or postdoctoral students conducting relevant work. For example, NASA made an award to aid in the development of climate change indicators related to heat waves in urban areas through its 2012 research announcement entitled "Research Opportunities in Space and Earth Sciences" that intended to, among other things, facilitate the application of scientific knowledge to management decisions.³⁹ Indicators developed through this program may be used by health officials to identify urban areas with increased vulnerabilities to health impacts due to a lack of cooling green spaces and other factors. Additionally, EPA sponsored a review of the effects of climate change on the indoor environment and health, which concluded, among other things, that climate change may worsen existing indoor environmental problems that are known to exacerbate illnesses such as asthma and allergies, and create new problems that have adverse health impacts.⁴⁰

Officials from some of the federal agencies included in our review told us that while their agencies have conducted or supported research that is useful for advancing understanding of climate change impacts to public health, the link to this topic is often indirect. For example, federally-funded research about health impacts from natural disasters, such as floods, does not always explicitly consider the associated impacts from climate change but can help advance understanding of these impacts, according to federal officials we spoke with. Appendix IV provides additional examples of research on or related to the risks of climate change to public health that some of the federal agencies included in our review have conducted or supported.

Providing Data and Decision Support Resources for Examining Risks

Federal agencies have provided some data and decision support resources—such as guidance and tools—that state and local officials, and others, can use to examine public health-related risks from climate change and potential actions to address these risks. Table 3 provides examples of these data and decision support resources.

Table 3. Examples of federal data and decision support resources for examining the risks that climate change poses to public health

Federal agency	Description of data or decision support resource
Environmental Protection Agency (EPA)	EPA published a software tool in 2010—referred to as the Climate Resilience Evaluation & Awareness Tool—to assist drinking water and wastewater utility owners and operators in understanding and addressing potential climate change risks at their utilities to continue to protect public health, among other reasons.
Department of Health and Human Services (HHS)	In December 2014, HHS published a best practices document to promote resilience of health care facility infrastructure to climate change impacts—primarily from extreme weather events, as part of its Sustainable Climate Resilient Health Care Facilities Initiative. To help users implement the guidance, the agency subsequently published an online toolkit with links to individual tools. In June 2015, HHS released its emPOWER map, an online interactive tool that displays information about vulnerable populations that rely on electricity-dependent medical equipment, to support state, local, and community partner emergency planning and response activities.
National Aeronautics and Space Administration (NASA)	NASA collects data on land surface temperature and other climate-sensitive environmental factors that may affect public health by, among other mechanisms, impacting the range of animals that can transmit harmful diseases to humans. The agency reports some data online and provides other data upon request.
National Oceanic and Atmospheric Administration (NOAA)	NOAA’s National Weather Service and its partners collect environmental data and provide decision support services to aid decision makers in their examination of the potential public health impacts of weather, water, and climate events.
U.S. Global Change Research Program (USGCRP)	In 2013, USGCRP introduced the Metadata Access Tool for Climate and Health, or MATCH, an online clearinghouse that provides links to thousands of government-held datasets related to health, the environment, and climate science.

Source: GAO. | GAO-16-122

Users of these data and decision support resources may include public health officials or decision makers with responsibility for managing systems that are necessary for protecting public health, such as hospital administrators or wastewater management system operators, among others. Other users may include researchers, community organizations, or other interested individuals. The following are two key interagency mechanisms that federal agencies leverage to provide climate and health data and decision support resources to potential users:

- **Data.gov.** In April 2015, data.gov, the federal government’s site for open data, launched a theme page on climate and health that provides information about data sources and tools maintained by federal agencies.⁴¹ The site includes links to data on climate, weather, and health from many federal agencies. One data source included on the theme page is CDC’s National Environmental Public Health Tracking Network, which includes heat-related health data, including national data on the number of extreme heat days and future projections of extreme heat.⁴² Another data source included on the theme page is NOAA’s Climate Data Online, which includes

data on precipitation amounts, as well as a mapping tool and other decision support resources.

- **The U.S. Climate Resilience Toolkit.** The toolkit is an online portal that is intended to help individuals, communities (including tribal nations), and others respond to risks from climate change. Human health is one of the topics highlighted in the toolkit.⁴³ One tool available in the toolkit is the Agency for Toxic Substances and Disease Registry's Social Vulnerability Index, which uses U.S. Census Bureau variables to identify communities that may need support in preparing for climate-related or other hazards or recovering from disasters, and includes a mapping feature and downloadable data. Another tool available in the toolkit is a software package developed by EPA that allows users to predict levels of disease-causing pathogens at specific beach sites, where outbreaks can result from climate change-related effects such as warming waters and intense precipitation.⁴⁴

CDC has also developed some decision support resources intended to help state and local public health officials identify and address risks from climate change. In June 2014, CDC officials authored a journal article which described a five-step risk management framework that the agency developed for health officials to use in preparing for the health effects of climate change.⁴⁵ In July 2014, CDC issued a more detailed guide for health departments on how to assess the vulnerability of their constituent populations to the health impacts of climate change—a critical step for health departments in planning for climate change risks to public health, according to CDC.⁴⁶ The guide includes a case study detailing how CDC conducted a vulnerability assessment on heat impacts in the state of Georgia. In addition, CDC's National Environmental Public Health Tracking Program published a communication toolkit in 2012 that focuses on the relationship among climate change, public health, and extreme heat—which is the only climate change-related area for which the tracking network provides data.⁴⁷ Among other things, the communication toolkit provides health officials and other potential users with key messages and tips for using social media to communicate effectively about this topic.

Communicating through Reporting and Outreach

Federal agencies in our review have communicated information about the risks that climate change poses to public health through reporting and outreach efforts directed at multiple audiences, such as public health officials and the general public. In several key communication efforts, federal agencies have collaborated to report on what is known about these risks. For example, in the third NCA published in May 2014, USGCRP reported on the impacts of climate change on the United States, including risks to human health. The report was the result of a large multiagency effort that included the 13 agencies participating in the USGCRP as well as other agencies that chose to support the production of the report.⁴⁸ It includes a chapter on human health—prepared collaboratively by officials from several federal agencies participating in CCHHG, as well as experts from outside the federal government—summarizing what is known about how climate change threatens human health and well-being, populations that are at greatest risk, the extent to which public health actions

can help address these risks, and opportunities to improve human health while combating climate change.⁴⁹ CCHHG is expanding upon this information in a report that is intended to provide a comprehensive, evidence-based, and, where possible, quantitative estimation of observed and projected climate change related health impacts in the United States. The report, referred to as the USGCRP Climate and Health Assessment, is being developed through a multiagency effort and is expected to be finalized in 2016.⁵⁰ The American Public Health Association, with the support of CDC, recently reported on threats that climate change poses to human health, and how state and local public health departments have responded to these threats using CDC resources.⁵¹ In addition to preparing reports, federal agencies have also reported on the risks that climate change poses to public health through their websites and through social media, and federal officials have reported on these risks in peer-reviewed journal articles and other publications.⁵²

Federal agencies have conducted outreach to inform public health officials, as well as the general public, about the risks that climate change poses to public health. Some ways in which federal agencies have recently done so include the following:

- In August 2014, HHS held a departmentwide briefing on climate change risks to public health.⁵³
- In December 2014, CDC addressed climate change in its Public Health Grand Rounds—a publicly-available webcast that is intended to foster discussion on major public health issues.⁵⁴

In addition, senior officials within HHS and EPA have also conducted outreach on certain occasions about the risks that climate change poses to public health. In April 2015, the Surgeon General spoke publicly about climate change impacts to health following a roundtable discussion on the topic with the President, the EPA Administrator, and others, and also used social media to solicit and respond to questions about health impacts from climate change. The EPA Administrator has also communicated about these risks to a variety of audiences, citing climate change as among the most significant threats to public health.⁵⁵ App. V provides additional information about federal activities related to climate change risks to public health.

STATE AND LOCAL HEALTH DEPARTMENTS HAVE USED CDC AND OTHER FEDERAL RESOURCES TO ADDRESS THE RISKS THAT CLIMATE CHANGE POSES TO PUBLIC HEALTH

Selected state and local health departments included in our review have used a CDC climate and health award that addresses the risks that climate change poses to public health, as well as other federal resources, to address and plan for the public health risks from climate change.

Selected Health Departments Have Used a CDC Award to Directly Address and Plan for the Risks that Climate Change Poses to Public Health

Sixteen state and two local health departments have used awards from CDC's Climate Ready States and Cities Initiative to address and plan for the risks that climate change poses to public health.⁵⁶ The initiative is the federal government's primary investment in supporting state and local health departments in addressing the risks that climate change poses to public health, and is the only HHS financial resource that has been offered to state and local public health departments that directly targets these risks. In fiscal year 2014, Initiative awards to state and local health departments totaled \$3.6 million, with individual awards averaging about \$200,000.⁵⁷ Figure 2 displays Initiative awardees as of fiscal year 2015.

Source: Centers for Disease Control and Prevention; Map Resources (map). | GAO-16-122

Figure 2. CDC Climate ready states and cities initiative awardees, fiscal year 2015.

CDC's Climate and Health Program administers the Climate Ready States and Cities Initiative. Under the initiative, CDC program staff are substantially involved in program activities, above and beyond routine grant monitoring. CDC activities for this program are described as providing ongoing guidance, resources, consultation, technical assistance, and training related to awardee activities.

Under the initiative, CDC requires awardees to implement CDC's Building Resilience Against Climate Effects (BRACE) framework—a five-step risk management process intended to help public health departments identify and prepare for the public health impacts of climate change by, among other things, incorporating atmospheric data and climate projections into public health planning. To implement the framework, CDC requires awardees to work with internal and external stakeholders to forecast climate trends, identify disease

risks and vulnerable populations, and develop action plans for addressing these risks, among other things. Figure 3 describes the five steps of the framework and provides examples of activities that can be included in its implementation.⁵⁸ CDC officials told us that they developed the BRACE framework to assist state and local health departments in preparing for the public health impacts of climate change. (App. VI provides information on the types of activities undertaken by awardees in implementing the BRACE framework, and app. VII provides information on activities by other selected state and local health departments).

Sources: GAO analysis of Centers for Disease Control and Prevention information and Art Explosion (image). | GAO-16-122

Note: According to CDC officials, the Building Resilience Against Climate Effects (BRACE) framework is iterative and enables the incorporation of learning into future decisions by encouraging users to revisit prior steps to reevaluate risks and management priorities.

^a According to CDC, qualitative methods may be used to provide a general impression of how climate change may affect the risk for certain outcomes, at least capturing general climatic trends and environmental exposures, population vulnerability, and expected human health impacts. Quantitative methods may be used, for example, to quantify existing climate and health exposure pathways, or to project disease impacts.

Figure 3. Steps and examples of activities conducted under CDC's building resilience against climate effects framework.

Under the initiative, CDC requires awardees to complete a range of activities that complement their work implementing the BRACE framework. For example, CDC requires that awardees take steps to increase awareness among the public and decision makers about the risks that climate change poses to public health, making use of available CDC resources.

Awardees provided examples of the types of guidance and support that CDC's Climate and Health Program has provided to assist them in implementing the BRACE framework and addressing climate and health information needs in their jurisdictions. For example, CDC created guidance for awardees on how to develop a Climate and Health Profile—a report detailing a jurisdiction's climate-related exposures, health outcomes of concern, and vulnerabilities of certain populations—a required component of the first step of the BRACE framework. CDC officials told us that they plan to issue guidance describing how to approach each step of the BRACE framework. As of June 2015, CDC has issued two guidance documents on the first step of the framework.⁵⁹ Awardees also told us about other types of support provided by CDC, including tools that CDC developed in response to awardees' specific requests for assistance, such as a database of peer-reviewed literature on climate change and public health impacts and a graphic summarizing the impacts of climate change to public health.⁶⁰ CDC has also organized several communities of practice among awardees as forums to discuss issues related to the implementation of the BRACE framework.⁶¹ According to CDC officials, some public health departments that have not received the Climate Ready States and Cities Initiative award have expressed interest in implementing the BRACE framework, and such departments are able to do so using the resources available on CDC's website.

Although awardees told us that they are in various stages of implementing the framework, they also noted that they have already observed a variety of benefits from the award. Specifically, awardees we spoke with told us that the CDC award has enabled them to work on climate change and health issues in a formalized way that would otherwise not have been possible given, for example, competing priorities and limited staff time. According to our analysis of awardee reports to CDC, nearly all 18 awardees have created a climate and health program with dedicated staff within their departments to work on this issue, although doing so is not a requirement of the award. Awardees also reported that the program allows them to address specific needs in their jurisdictions and consider certain areas of interest while implementing the framework. For example, some awardees in state health departments told us that they have provided subawards to a small number of local health departments in their jurisdictions to participate in the implementation of the BRACE framework, such as by providing feedback on the usefulness of materials developed by the state, or to develop their own initiatives on or related to climate change and public health. Officials in these states told us that the award allows staff in the local jurisdictions to spend time considering the risks that climate change poses to public health and how these risks may impact existing priorities in their health departments. Additionally, some awardees have identified specific risks that climate change poses to public health and are interested in exploring these issues in further detail. For example, some awardees are examining potential health affects related to climate change impacts on food security—that is, the availability and affordability of nutritious and quality foods.

Furthermore, awardees told us that the CDC award has allowed for their programs to build relationships and engage with partners, such as officials from other departments in their jurisdictions or regional partners from federal agencies, in ways that could not be accomplished without such awards or without a formalized climate and health program. For example, officials from the New York City Department of Health and Mental Hygiene told us that through the department's climate and health program, they worked collaboratively with their regional National Weather Service office to study the appropriateness of the thresholds

used to issue heat advisories and warnings. According to these officials, the National Weather Service had been using a Heat Health Watch and Warning System in addition to heat index forecasts to determine when to issue heat advisories and warnings; however, health officials were concerned that this method was not sensitive enough for use in predicting public health outcomes during excessive heat events.⁶² The health department completed a retrospective study of heat-related deaths to evaluate metrics that could be used to estimate risks, and it found that maximum heat index is a useful metric for assessing public health risks due to hot weather in New York City. The officials said that they have changed the threshold at which warnings are set as a result of this study, and they have continued to develop a working relationship with the National Weather Service.

Selected Health Departments Reported Leveraging Other Federal Resources to Address and Plan for Risks

State and local public health officials we interviewed reported leveraging a variety of other federal resources, including funding and information sources, to address and plan for the risks that climate change poses to public health. In most cases, these federal resources were not specifically designed for addressing and planning for these risks, but the resources could be used in ways that support such efforts. State and local public health officials we interviewed most commonly mentioned leveraging resources provided by CDC's National Environmental Public Health Tracking Program to support their work in addressing and planning for the public health risks of climate change. CDC's Tracking Program made awards to 25 states and one city to develop local tracking networks, analyze data on local environmental exposures and related health outcomes, and supply selected data to a national tracking network.⁶³ The national network includes indicators on climate change, among other environmental hazards, related to extreme heat exposure.⁶⁴ State and local health officials we interviewed reported that this award provides an important core source of funding for data infrastructure and environmental health surveillance activities in their jurisdictions, which can be leveraged to include activities such as monitoring patterns of heat-related illness. Awards provided to state and local health departments for the tracking program vary; in fiscal year 2014, awards totaled \$22.6 million to participating states and localities, ranging from about \$500,000 to \$1.2 million, with an average award of about \$870,000.⁶⁵

State and local health officials also provided examples of how their jurisdictions have leveraged funding resources from other CDC programs to address and plan for the risks that climate change poses to public health. For example, state and local health officials told us that they have leveraged awards from CDC's Public Health Emergency Preparedness program—which provides state, local, tribal, and territorial health departments across the country with resources to build public health preparedness capabilities—to help consider climate change in emergency preparedness planning or develop systems that can be used to monitor climate-related public health risks. Awards provided to state and local health departments vary; in fiscal year 2014, for example, awards ranged from \$325,000 to approximately \$42.5 million, with an average award of approximately \$9.9 million and a total of about \$611.8 million.⁶⁶ Climate change is not a specific focus of the program, but CDC officials responsible for administering this program told us that awardees have flexibility in determining how to use

the funds while meeting CDC's requirements.⁶⁷ State health officials also told us that they have used awards from CDC's National Institute for Occupational Safety and Health to consider the impacts of climate change on worker safety and health, such as by monitoring heat-related illnesses and deaths among worker populations or specific industries.⁶⁸ Officials from the National Institute for Occupational Safety and Health also noted that, while climate change is not a specific focus of the program, the award could be used to support activities in this area.

Some public health officials we interviewed also reported leveraging federal resources from agencies other than from CDC to address or consider the risks that climate change poses to public health. Specifically, officials provided examples of other awards and informational resources that they had used in their work on this issue. For example, an official from one state told us that the state used an award from U.S. Geological Survey to assess the vulnerability and health risks of the state's watersheds to flooding and drought under a changing climate. Some state and local health officials reported using the health and regional chapters of USGCRP's third NCA as key sources of information. Some officials also told us that they have relied on a variety of NOAA information resources, such as those provided through NOAA's National Centers for Environmental Information or through NOAA-funded Regional Integrated Sciences and Assessment teams.⁶⁹ For example, one state health official told us that the state has relied on support from a NOAA Regional Integrated Sciences and Assessment team to translate technical information about climate change. In conducting work to address the risks that climate change poses to public health, local health officials from one jurisdiction also provided an example of using demographic information from the American Community Survey—an official U.S. Census Bureau survey that is part of the Decennial Census Program—to identify populations in its locality that are vulnerable to the health-related impacts of climate change.

STATE AND LOCAL HEALTH OFFICIALS IDENTIFIED MULTIPLE CHALLENGES, SOME OF WHICH THEY SAID COULD BE ADDRESSED BY FEDERAL ACTION

When asked to identify challenges related to their work planning for and addressing the risks that climate change poses to public health, state and local public health officials we interviewed identified challenges that we grouped into the three most frequently reported themes, noting that some of these challenges could be addressed by federal action, while others could not. According to state and local officials, they face challenges communicating about the risks that climate change poses to public health. Officials identified related opportunities for federal agencies to enhance public understanding of these risks. The officials also stated that they face challenges in identifying potential health risks of climate change, for example, as a result of research gaps. Officials said that federal agencies may be able to address this challenge by continuing to advance research and enhance decision support resources. Finally, state and local public health officials said they face other challenges that federal action may not be able to address, such as having insufficient data on health impacts in areas where agreements between states and hospitals limit access by health departments.

Selected Health Officials Face Challenges Communicating about the Risks That Climate Change Poses to Public Health and Identified Opportunities for Federal Action

According to our discussions with selected state and local health officials, officials face challenges communicating about the risks that climate change poses to public health, in part because of limited awareness about climate change as a public health issue. The officials also identified opportunities for federal agencies to address these communication challenges.

Challenges Identified

Selected state and local health officials told us during interviews, site visits, and small group discussion sessions that they face challenges resulting from limited awareness about climate change as a public health issue within their own health departments, among other state and local partners, such as other agencies in their jurisdictions, and among the public. As we have previously found, public awareness can play an important role in the prioritization of climate change adaptation efforts.⁷⁰

In addition, if public health officials are aware of the risks that climate change poses to public health, they can better assess the importance of these risks and allocate resources appropriately. However, health department leadership and staff are often not aware of the public health impacts of climate change, or do not understand how the issue fits into the health department's priorities, according to state and local health officials.⁷¹ This observation is consistent with results from a 2012 NACCHO survey of 174 local health department officials, which showed that just over one-third of respondents thought that other relevant senior managers in their health departments were knowledgeable about the potential public health impacts of climate change.⁷²

Some local health officials also reported that officials from other sectors of government in their jurisdictions, such as environmental agencies responsible for climate change adaptation planning efforts, have a limited awareness of climate change as a public health issue. This has resulted in health officials having limited involvement in climate change adaptation planning within their localities, according to officials we interviewed. Some officials believe that progress has been made in this area in recent years, but, according to our review of a 2014 analysis of states' climate change adaptation planning activities, only about one-quarter of all states have incorporated public health considerations into their statewide climate change adaptation plans.⁷³

In addition, health officials told us that stakeholders and the public have limited awareness about climate change as a public health issue, in part because climate change has historically been framed as an environmental issue. State and local health officials discussed climate change impacts on health as an emerging issue that they became aware of within the last decade, in part as a result of educational efforts of the American Public Health Association. In 2008, for example, the association made climate change a focus of its National Public Health Week, issuing communications to highlight climate change as a public health issue.⁷⁴

State and local health officials also told us that they face challenges in communicating or enhancing awareness about projected changes to local climate that can impact public health because of the complexity of the issue.⁷⁵ Specifically, officials told us that it is difficult to

develop messages about climate change impacts on health because of uncertainties inherent in climate change projections. For example, officials from one state health department told us that the state has faced challenges describing climate projections for its jurisdiction in a way that is accurate but not overly technical, while adequately acknowledging the uncertainties of these projections. State and local health officials also said that it is challenging for them to communicate about the risks that climate change poses to public health because some of the potential effects have not yet been observed in their jurisdictions and, therefore, are not perceived by the public as risks. For example, officials in some states that do not frequently experience heat waves told us that they face challenges convincing their constituents that the risks of heat-related illnesses will increase. Officials told us that they have used a variety of strategies to attempt to interest their constituents and stakeholders in these risks, such as framing the issue as planning for emergency preparedness or severe weather events. However, state and local health officials find it difficult to communicate and bring attention to long-term issues, such as climate change, when there are more immediate public health concerns drawing attention, such as the 2014 Ebola virus outbreak.⁷⁶

Opportunities Identified

State and local health officials, as well as representatives from associations representing these officials, identified opportunities for federal action to help address challenges the officials face in communicating about the risks that climate change poses to public health. These opportunities were generally in two areas: enhancing public awareness on climate change as a public health issue, and providing guidance and tools on how to communicate about this issue.

Concerning enhancing public awareness, state and local health officials, as well as representatives from associations representing these officials, told us that federal agencies could help address this challenge by taking a sustained leadership role in enhancing public and stakeholder awareness and understanding. Specifically, officials told us that a federally-led public awareness campaign on this issue could assist in informing decision makers and the public. They also said a campaign could help and provide legitimacy to the work of public health officials in addressing and planning for these risks. Officials particularly pointed to the need for a sustained leadership role from HHS and its component agencies, which could draw on the department's experience from engaging in previous successful public health campaigns, such as the campaign to reduce tobacco use. In a November 2014 report, the President's State, Local, and Tribal Task Force on Climate Preparedness and Resilience also recommended actions that federal agencies should take to increase climate literacy and public awareness, among other things.⁷⁷ These actions included coordinating federal communications on climate change to develop clear, consistent and unified messages, and ensuring that communications resources are accessible to state and local governments. (See app. VII for a summary of the task force's health-related recommendations.)

Federal officials, including those from HHS, told us that they are taking steps to enhance public awareness. For example, as previously mentioned, the White House held a climate change and health summit in June 2015, which included the participation of the U.S. Surgeon General, the HHS Assistant Secretary for Preparedness and Response, and the EPA Administrator. In addition, CDC officials told us that through awards the agency provides, the FrameWorks Institute is developing a series of fact sheets for the general public that explain various impacts of climate change on human health.⁷⁸ In its 2014 Climate Adaptation Plan,

HHS reported that it considers climate change to be one of the top public health challenges of our time, and it noted that its Office of the Assistant Secretary for Health will develop a climate change communication and outreach strategy to, among other things, promote outreach and awareness among its stakeholders about climate change and its impact on public health.⁷⁹ The plan further notes that outreach and communication to at-risk populations will be a significant part of this strategy, and that the department will leverage its comprehensive network of stakeholders involved in the receipt or delivery of health and human services to disseminate climate change and health information. HHS reported in its Strategic Sustainability Performance Plan that the strategy was to be developed by the fall of 2014.⁸⁰ In March 2015, a senior HHS official from the HHS component responsible for developing this strategy told us that limited progress had been made in developing the strategy, and that the strategy was not anticipated to be formalized in a written document. However, in July 2015, HHS officials told us that they plan to refine and document the strategy over the next 12 months.

Concerning guidance and tools, state and local health officials, as well as a representative from an association representing them told us it would be helpful if federal agencies, including CDC, developed communications guidance on a number of topics. For example, they said they could benefit from guidance on how to frame climate change as a public health issue or communicate based on best practices from the social sciences. They also suggested the development of communication tools, such as talking points or training on how to communicate about this issue. Because protecting public health requires the participation of a variety of stakeholders—including state and local public health departments and other state and local entities—enhancing stakeholder awareness and understanding about climate change as a public health issue could bolster state and local preparedness for the risks that climate change poses. In addition, as noted earlier in this report, enhancing awareness among the public and decision makers about the risks that climate change poses to health is a requirement of the Climate Ready States and Cities Initiative. According to state and local health officials, including Initiative awardees, communication guidance and tools would help them enhance stakeholder awareness and understanding of the risks climate change poses to public health.

CDC has developed limited guidance regarding communicating the risks that climate change poses to public health for state and local health officials. CDC has developed a toolkit related to communicating the connections between climate change, extreme heat, and health. However, the content of this document is focused on how awardees and partners of the National Environmental Public Health Tracking Network can use Tracking Network data to communicate about this issue, and is therefore not as applicable to a wider audience.⁸¹ CDC officials were not aware of any other agency guidance documents on communicating about the risks climate change poses to public health.⁸² Officials from CDC's Climate and Health Program acknowledged that a commitment to communicating about the risks that climate change poses to public health is needed, and they identified some actions to help Climate Ready States and Cities Initiative awardees address this challenge, such as reviewing and sharing research findings on best practices for communicating about climate change and providing technical assistance to state and local health departments regarding communication upon their request. However, these officials also told us that they do not currently have plans to develop communication guidance for state and local health departments on how to communicate about climate change because they do not have the resources or capacity to

develop such guidance at this time. CDC officials told us that they have been focusing on assisting awardees with resolving methodological and data issues related to implementing the BRACE framework, such as identifying models for use in developing projections of climate change in their jurisdictions.

As we noted earlier, the agency's Climate and Health Program supports state and local health department efforts to plan for and address the health risks posed by climate change. CDC's website states that the program's core functions involve translating climate change science to inform health departments and communities, serving as a credible leader in planning for the public health impacts of climate change, and creating decision support resources to assist officials in preparing for climate change.⁸³ As the administrator of the Climate Ready States and Cities Initiative, CDC is to provide ongoing guidance, resources, and technical assistance, among other things, related to awardee activities. Because CDC requires that awardees of this initiative take steps to enhance public awareness of the risks that climate change poses to human health, developing communications guidance would support their efforts. While CDC's current resources are focused on addressing methodological and data issues related to the implementation of the BRACE framework, it is also critical for the agency to establish a plan describing when it will develop future communications guidance, to help ensure that health officials have the tools they need to effectively implement the BRACE framework and address required aspects of the award.

Selected Health Officials Face Challenges Identifying Potential Health Risks of Climate Change and Identified Opportunities for Federal Action

According to our discussions with selected state and local health officials, they face challenges identifying potential health risks from climate change and have identified related opportunities for federal action. Specifically, officials noted how gaps in research have made it difficult for them to understand and plan for potential health impacts. For example, some state and local public health officials said that limited research has been conducted on how climate change may affect certain aspects of public health, such as the spread of vector-borne diseases, the costs of climate change impacts on human health, and the effectiveness of specific management options. Other officials we interviewed told us that they had difficulty using some of the climate-related data that federal agencies have made available for decision makers. Officials we interviewed explained that they typically do not have the scientific or technical expertise to fully understand or use some federal data, particularly those related to climatology. Public health officials have generally not been trained in using geographic information systems, atmospheric data, and climate projections, according to officials.⁸⁴ In addition, conducting analyses with these data can be complex and time-intensive. Consequently, they said that the availability of technical assistance in using such data, as well as in translating the results so that officials can apply them at the local level, has been very helpful.⁸⁵

State and local public health officials we interviewed said that federal agencies could help address these challenges by continuing to advance the research they support, and by enhancing decision support resources, including resources to assist decision makers in using federal datasets. State officials noted that an expansion of interagency research opportunities

on the public health impacts of climate change, which is a crosscutting research area, could be helpful. State and local public health officials we interviewed said that federal agencies could also enhance the decision support resources they provide, including through technical assistance that would better position public health departments to effectively use available datasets. For example, a Climate Ready States and Cities Initiative awardee said that it would be helpful if CDC could provide awardees with programming language to assist them in using federal datasets to assess health vulnerabilities associated with climate change.

Officials from federal agencies told us about actions that they have taken or that they have planned that could help address some of these challenges. Specifically, federal officials have acknowledged the need for additional research on the public health impacts of climate change and have taken some steps to fill those needs. In 2010, an ad hoc interagency working group on climate change and health developed a white paper summarizing research needs on the human health effects of climate change.⁸⁶ The intent of this paper was to provide a baseline picture of research needs in this area that agencies could then build upon as new information became available, according to the paper. Subsequently, NIH officials analyzed the agency's portfolio of research on climate change and health, and summarized their results in an article published in 2013.⁸⁷ The article includes a discussion of challenges related to conducting this research and opportunities to advance the research, including opportunities to take a multidisciplinary approach through enhanced interagency research opportunities.⁸⁸ More recently, in an April 2015 *Federal Register* notice, EPA, on behalf of USGCRP, announced that a draft of the CCHHG assessment of climate change impacts on health was available for comment.⁸⁹ According to the CCHHG co-chairs, the report contains results that should advance the research in some needed areas, and is likely to include some information on research needs. The CCHHG co-chairs told us that they hope to use information on research needs included in the final assessment to help inform the development of a prioritized and focused research agenda for use in addressing research needs. CCHHG officials also told that they would like to continue to help foster a collaborative interagency approach to researching climate change impacts on health.

Federal agencies, such as HHS, EPA, and NOAA, have also recently taken steps to enhance data and decision support resources available to state and local decision makers, for example, by enhancing air quality surveillance and creating a national heat health information system. These enhanced resources may address some needs of state and local decision makers. CCHHG officials said that they have plans to solicit feedback from state and local decision makers about these enhanced decision support resources through town hall meetings and other mechanisms.

Selected State and Local Health Officials Face Other Challenges That Federal Action May Not Be Able to Address

According to selected state and local public health officials we interviewed, they face a range of other challenges related to planning for and addressing the health impacts of climate change that federal action may not be able to address. For example, they said that insufficient data and inadequate resources impede their ability to address or plan for these risks. While some federal programs collect local data and provide financial resources to selected states and

localities, such as CDC's National Environmental Public Health Tracking Program, the federal government does not collect local data on climate impacts or health outcomes in all locations, and does not make awards to support the climate and health activities of all state and local health departments.

State and local public health officials told us that some environmental surveillance data that could help inform research on the health risks of climate change—such as data on air quality, water quality, and pollen—are often not collected by their states and localities given limited surveillance systems. Additionally, state and local officials explained that some health outcome data can be difficult to obtain. State officials explained that their access to health outcome data, such as the medical conditions cited for emergency room visits, is limited by agreements that states have with hospitals regarding the amount and type of information that hospitals will share with state officials.

Some state and local officials told us that their health departments did not have dedicated staff or funding to address and plan for climate change impacts or that their staff resources and funding were not sufficient for maintaining the ideal quality or quantity of work in this area. These statements are consistent with findings from NACCHO's 2012 survey of local health department officials, in which less than 10 percent of respondents said that their health departments had sufficient resources to effectively protect local residents from the health impacts of climate change, and less than 20 percent of respondents said their health departments had sufficient expertise to assess the potential impacts from climate change.⁹⁰

CONCLUSION

Federal agencies have taken steps to enhance understanding about the risks of climate change to public health. They have also supported state and local efforts to address and plan for these risks, in keeping with an executive order that calls on federal agencies to provide them with data, information, and decision support tools on climate preparedness and resilience. Nevertheless, state and local officials face challenges resulting from limited awareness of climate change as a public health issue among their own departments and the public. As we have previously found, public awareness can play an important role in the prioritization of work on climate change. HHS has acknowledged climate change as one of the top public health challenges of our time and is developing a climate change communication and outreach strategy, which has been delayed by over a year, but is expected to be finalized by July 2016.

CDC requires public health departments participating in its Climate Ready States and Cities Initiative to take steps to raise public awareness about the risks that climate change poses to public health, and also engage stakeholders in their planning. As the administrator of the Climate Ready States and Cities Initiative, CDC is to provide ongoing guidance, resources, and technical assistance to support state and local health department work on this issue. Although the agency has provided guidance on some topics, such as extreme heat events, it has not provided specific guidance on how public health departments should communicate about the risks that climate change poses to public health. Officials from CDC's Climate and Health Program acknowledged that a commitment to communicating about the risks that climate change poses to public health is needed. However, the agency does not

currently have plans to develop guidance on this topic, as it has been focused on other priorities. Issuing such guidance would also be in line with the core functions of CDC's Climate and Health Program, which include translating climate change science to inform communities. By developing such guidance, CDC may help public health departments better meet the requirements of the Climate Ready States and Cities Initiative and better position all health departments to make progress in planning for the health impacts of climate change.

RECOMMENDATION FOR EXECUTIVE ACTION

To enhance HHS's ability to protect public health from the impacts of climate change, we recommend that the Secretary of HHS direct CDC to develop a plan describing when it will be able to issue climate change communication guidance to state and local health departments, to better position relevant officials to effectively communicate about the risks that climate change poses to public health and address requirements of the Climate Ready States and Cities Initiative.

AGENCY COMMENTS AND OUR EVALUATION

We provided a draft of this product to HHS, EPA, NOAA, USGCRP, the Council on Environmental Quality, the Department of the Interior, and the National Science Foundation for comment. In its written comments HHS stated that CDC generally concurred with our recommendation. CDC noted its plans to develop and issue climate change communication guidance to state and local health departments after HHS finalizes its climate change communication and outreach strategy, which is expected by July 2016. CDC stated that it would use HHS's strategy to inform their development of guidance, and to build off of the same strategy. CDC said that the agency currently provides support and technical assistance to state and local health departments regarding communication upon their request, and would continue to do so while HHS finalizes its strategy. CDC remarked that the agency is also working with partner and professional organizations to disseminate messages on the health impacts of climate change.

We also received technical comments from HHS, EPA, NOAA, USGCRP, the Council on Environmental Quality, the Department of the Interior, and the National Science Foundation, which we incorporated as appropriate

APPENDIX I: LIST OF AGENCIES AND STAKEHOLDERS INTERVIEWED

We interviewed officials from federal, state, and local government agencies, as well as representatives of stakeholder groups involved in public health and climate change.

Government Agencies

Federal Agencies and Entities

1. Department of Commerce, National Oceanic and Atmospheric Administration
2. Department of Defense, Defense Health Agency
3. Department of Health and Human Services
 - Office of the Assistant Secretary for Preparedness and Response
 - Centers for Disease Control and Prevention
 - Indian Health Service
 - National Institutes of Health
 - Office of the Assistant Secretary for Health
4. Department of Homeland Security
 - Federal Emergency Management Agency
 - Office of Health Affairs
5. Department of the Interior
 - Bureau of Indian Affairs
 - Office of Insular Affairs
 - U.S. Geological Survey
6. Environmental Protection Agency
7. National Aeronautic and Space Administration
8. National Science Foundation
9. Smithsonian Institution
10. United States Department of Agriculture
 - Agricultural Marketing Service
 - Animal and Plant Health Inspection Service
 - Agricultural Research Service
 - National Institute of Food and Agriculture
 - Economic Research Service
 - Forest Service
 - Natural Resources Conservation Service
 - Office of the Chief Economist
11. United States Global Change Research Program
12. Council on Environmental Quality

State Public Health Departments

1. Alaska
2. Arizona
3. California
4. Florida
5. Hawaii
6. Illinois
7. Louisiana
8. Maine
9. Maryland
10. Massachusetts
11. Michigan
12. Minnesota
13. New Hampshire
14. New York
15. North Carolina
16. Oregon
17. Rhode Island
18. Utah
19. Vermont
20. Washington
21. Wisconsin

Local Public Health Departments

1. Baltimore (MD)
2. Benton County (OR)
3. Columbus (OH)
4. Dallas County (TX)
5. Houston (TX)
6. Multnomah County (OR)
7. New York City (NY)
8. Portsmouth (VA)
9. Salt Lake County (UT)
10. San Diego County (CA)
11. San Francisco (CA)
12. San Luis Obispo County (CA)
13. Shelby County (TN)
14. Summit County (OH)
15. Toledo-Lucas County (OH)
16. Washington County (MD)
17. Wicomico County (MD)

Stakeholder Groups

1. American Lung Association
2. American Public Health Association
3. Association of State and Territorial Health Officials
4. Council of State and Territorial Epidemiologists
5. George Mason University Center for Climate Change Communication
6. Georgetown Climate Center
7. Health Care Without Harm
8. National Association of County and City Health Officials
9. National Resources Defense Council
10. Public Health Institute
11. Trust for America's Health
12. Yale Climate and Energy Institute
13. Selected Lead Authors of the Third National Climate Assessment's Chapter on Human Health⁹¹

APPENDIX II: SUMMARY OF ACTIONS ANNOUNCED BY THE ADMINISTRATION IN APRIL 2015 TO ADDRESS THE HEALTH IMPACTS OF CLIMATE CHANGE

In April 2015, the administration announced a series of actions and commitments that were intended to enhance the nation's ability to understand, communicate, and reduce the health impacts of climate change.⁹² Specifically, the administration announced the following 12 actions that it plans to take to address this issue:

1. hosting a climate change and health summit at the White House;
2. issuing a report highlighting actions taken by state and local leaders to reduce the impact of climate change on public health;⁹³
3. releasing a health care facilities toolkit consisting of fact sheets, checklists, case studies, and other resources to assist local decision makers in promoting resilient health care infrastructure;⁹⁴
4. circulating a draft climate and health assessment report that is intended to synthesize the best available information on the public health impacts of climate change;⁹⁵
5. holding a community, culture, and mental health workshop to identify factors that enhance resilience to climate change;
6. integrating climate considerations into the Department of the Interior's health and safety policies;
7. hosting a climate and health data challenge, whereby coders, analysts, and researchers will use available government datasets to generate insights into unresolved questions about the health impacts of climate change;
8. offer climate and health data to participants during the national day of civic hacking (June 6, 2015) to encourage participants to develop new climate and health solutions;

9. improving air quality data with the Environmental Protection Agency's release of six new village green stations that measure air quality and meteorological data;
10. challenging researchers to develop new models to forecast epidemics of dengue and other infectious diseases through the consolidation of federal and nonfederal data sets;
11. awarding prizes to those who have developed predictive modeling capabilities that can assist government and health organizations to predict the spread of chikungunya, a vector-borne disease; and
12. measuring nutrient pollution through a competition whereby federal datasets are leveraged to develop educational and decision support resources.

Additionally, the administration announced that it has secured commitments with 14 businesses and other organizations to collect and share data regarding the health impacts of climate change. For example, Microsoft has committed to improve vector-borne disease surveillance capabilities by developing and deploying drones that are capable of collecting large amounts of mosquitos and automatically analyzing them for various pathogens. Finally, the administration announced that a coalition of deans from 30 medical, nursing, and public health schools had committed to train their students to address the health impacts of climate change.

APPENDIX III: SUMMARY OF ACTIONS ANNOUNCED BY THE ADMINISTRATION IN JUNE 2015 TO ADDRESS THE HEALTH IMPACTS OF CLIMATE CHANGE

In June 2015, the administration announced a set of actions and commitments that were intended to protect our communities from the health impacts of climate change.⁹⁶ Specifically, the administration announced the following actions to address this issue:

1. creation of a map tool by the Department of Health and Human Services to improve the ability of health officials and emergency managers to rapidly identify residential areas where people who depend on electricity to power life-critical durable medical equipment live;
2. development of a national integrated heat health information system by the Centers for Disease Control and Prevention and the National Oceanic and Atmospheric Administration, which is intended to provide a suite of decision support resources that better serve public health needs;
3. launch of a climate and health innovation challenge series by the National Institutes of Health and others to promote innovative approaches and highlight technologies available for understanding the health implications of climate change and improving resilience to adverse effects;
4. creation of a climate change impacts subcommittee within the Federal Interagency Working Group on Environmental Justice, and the workgroup's launch of a climate justice initiative that is focused on incorporating equity into climate adaptation planning;

5. announcement of a local climate and energy webcast series on climate change, heat islands, and public health, to be hosted by the Environmental Protection Agency;
6. plans to highlight examples of policy actions related to children's health during national Children's Health Month;
7. a commitment by CDP, a private organization, to release publicly disclosed data from 61 U.S. cities that summarize the climate risks that the cities are facing and the actions they are taking to improve resilience; and
8. an expansion in the number of medical, public health, and nursing schools that have committed to educate and train their students about the risks of climate change to public health.

APPENDIX IV: EXAMPLES OF CLIMATE CHANGE AND HEALTH RESEARCH CONDUCTED OR SUPPORTED BY FEDERAL AGENCIES

Federal agencies conduct or support research on a range of topics that can enhance understanding of the risks that climate change poses to public health. In conducting our work, we interviewed officials from some federal agencies involved in the United States Global Change Research Program's Interagency Crosscutting Group on Climate Change and Human Health. Specifically, we spoke with officials from those agencies whose focus was on understanding climate change risks to populations within the United States. Table 4 provides examples of research some of the federal agencies involved in this group have conducted or supported on or related to the risks that climate change poses to public health.

Table 4. Examples of federal agencies supporting or conducting research on or related to the risks that climate change

Federal agency	Examples of agency actions to support or conduct research
Environmental Protection Agency (EPA)	• Through its Science to Achieve Results program, EPA has made research awards to assess climate change impacts to health, including those related to air and water quality as well as impacts to tribal populations. For example, one project reviewed the relationship between extreme weather events and combined sewer overflows, which can enhance understanding of how climate change may affect risks from water-borne diseases associated with such overflows. Another project assessed a tribe's vulnerability to waterborne disease risks. • EPA has conducted research on how weather events associated with climate change—including heat, flooding and droughts—alter the risk of health impacts associated with air and water pollution, heat exposure, allergens, and water-borne and infectious diseases. For example, the agency's National Health and Environmental Effects Research Laboratory has conducted research on how the combination of air pollutants and elevated temperatures affect human health, including in populations that may be especially sensitive to such effects. • EPA has published information on observed trends in health-relevant indicators of climate change, including changes in high and low temperatures, heat-related mortality, Lyme disease, length of the ragweed pollen season, and extreme weather events.
Department of Health and Human Services (HHS)	• NIH has made research awards on or related to climate change and public health. For example, beginning in FY 2013, NIH made an award for a research project on climate change and heat-related morbidity among vulnerable populations in Atlanta.

Table 4. (Continued)

Federal agency	Examples of agency actions to support or conduct research
National Aeronautics and Space Administration (NASA)	• NASA assisted the New York City Panel on Climate Change in researching the impacts of climate change on New York City and the surrounding metropolitan region, including impacts to public health.
National Oceanic and Atmospheric Administration (NOAA)	• Some of NOAA’s regional research teams (referred to as Regional Integrated Science and Assessment teams) have partnered with local decision makers to provide actionable information related to the health impacts of climate change. For example, the team for the Great Lakes region has worked with local decision makers to develop a tool intended to help decision makers examine options for reducing morbidity and mortality related to extreme heat events in Michigan under changing climate conditions. • NOAA’s Ecological Forecasting Roadmap team partners with federal and state decision makers to integrate climate information into predictions for harmful algal blooms and pathogens such as <i>vibrio parahaemolyticus</i>.
National Science Foundation (NSF) ^a	• Since 2000, NSF has led a collaborative effort with other federal agencies to solicit proposals for research on the ecology and evolution of infectious disease. Among other things, the influence of environmental factors such as climate is listed as a factor that researchers may wish to consider as they design their work. Through this program, NSF made a research award focused on examining why the occurrence of Lyme disease varies significantly across regions of the eastern United States where blacklegged ticks, which transmit the disease to humans, are found. The researchers intended, in part, to help advance predictions of how climate change could impact the risk associated with Lyme disease.
Smithsonian Institution	• Researchers with the Smithsonian Institution have conducted research on the relationship between environmental factors, including rainfall and vegetation cover, and infestations of fleas, which are known vectors for a variety of pathogens, including plague.
U.S. Department of Agriculture	• The Department’s Agricultural Research Service has conducted research on the relationship between climate change and a variety of factors that can impact human health, including crop growth, levels of allergenic plant pollens, food availability, and water quantity.

Source: GAO. | GAO-16-122

^a NSF does not typically make awards for research on the cause, diagnosis, or treatment of physical or mental disease in human beings, as research in these areas is supported by the National Institutes of Health.

APPENDIX V: EXAMPLES OF FEDERAL AGENCY ACTIVITIES ON OR RELATED TO THE PUBLIC HEALTH IMPACTS OF CLIMATE CHANGE

Federal agencies have conducted a range of activities related to understanding, communicating, and managing for the public health impacts of climate change. In conducting our work, we interviewed officials from 26 federal agencies, including some of those involved in the United States Global Change Research Program’s Interagency Crosscutting Group on Climate Change and Human Health. Specifically, we interviewed officials from agencies whose focus was on understanding or managing for climate change risks to populations within the United States. We also interviewed officials from the United States Global Change Research Program and the Council on Environmental Quality. Table 5 provides information about activities conducted by these selected agencies.

Table 5. Examples of Activities Conducted by Selected Federal Agencies on or Related to Public Health Impacts of Climate Change

Department and component agency or office	Summary of work related to climate change and health	Examples of activities
Department of Commerce		
National Oceanic and Atmospheric Administration (NOAA)	Collects and provides data, collaborates in research, and develops decision support resources to aid decision makers in examining and addressing the potential health impacts of climate-related events.	• Develops climate change projections, including those used in the third National Climate Assessment. • Maintains the Climate.gov portal, which includes scientific information and materials about climate change, including impacts to public health. • Works with public health officials through its National Weather Service to revise thresholds for issuing heat alerts, and through its Climate Program Office to understand and provide climate information as part of an integrated heat health information system. • Through its National Weather Service, works with federal, state, and local authorities to support hospital and community preparedness efforts. • Developed the Coastal Flood Exposure Mapper, a tool that allows users to access maps showing populations, places, and natural resources exposed to coastal flood hazards.
Department of Defense		
Defense Health Agency	Routinely assesses and addresses health risks to personnel through disease surveillance activities, including health risks related to extreme heat and cold.	• Plans to review and, as needed, modify health surveillance programs to better integrate climate change considerations into the department's efforts to address health and safety risks to its personnel.
Department of Health and Human Services		
Office of the Assistant Secretary for Health	Coordinates intra- and interagency activities related to climate change and health.	• Plans to develop a climate change communication and outreach strategy. • Held a departmentwide briefing on climate change and health in August 2014.
Assistant Secretary for Preparedness and Response	Leads the department's efforts to prevent, prepare for, and respond to public health emergencies, some of which may stem from climate change	• Leads science preparedness efforts aimed at establishing and sustaining a research framework that communities can leverage to better identify, collect, and analyze data and information that may be available only before, during, or immediately following a public health emergency. • Provides awards for examining the long-term recovery of health systems and communities impacted by Hurricane Sandy. • Provides federal support, including medical professionals, through its National Disaster Medical System, to augment state and local capabilities during an emergency or disaster. • Through its emPOWER map, provides data regarding vulnerable populations that rely upon electricity-dependent medical equipment, to support state, local and community partner emergency planning and response activities.
Centers for Disease Control and Prevention	Works with state and local health departments through a variety of programs to enhance capacity to protect public health, including from the impacts of climate change.	• Through its Climate and Health Program, manages the Climate Ready States and Cities Initiative, which provides awards and technical resources to 18 state and local health departments to incorporate climate change considerations into public health planning, including by implementing a five-step risk management framework.

Table 5. (Continued)

Department and component agency or office	Summary of work related to climate change and health	Examples of activities
		• Supports a network of 26 health departments to collect and make available health, exposure, and hazard data, including on climate change indicators, measures, and data related to extreme heat, through the National Environmental Public Health Tracking Program. • Works with state and local health departments to prepare for and respond to public health emergencies, including by providing awards for emergency preparedness planning to all 50 states, eight territories, and four large cities. • Through its National Institute for Occupational Safety and Health, established a climate change initiative to, among other things, make recommendations for worker safety and health improvements related to climate change. The Institute also seeks to identify workers and facilities at an increased risk to severe weather events.
Indian Health Service	Provides primary health care and disease prevention services to American Indian and Alaska Native people.	• Provided an award to the Alaskan Native Tribal Health Consortium to assess the impacts of climate change on sanitation facilities, including determining data gaps for health- and safety- related parameters.
National Institutes of Health	Funds research on the health impacts of climate change.	• Issued a trans-institute research solicitation in 2010 on the public health impacts of climate change that resulted in awards for 21 new research projects. • Led an ad hoc interagency working group in developing a white paper on research needs for health impacts that may be exacerbated by climate change. • Through its Worker Training Program, hosted a workshop on the health risks that hazardous waste workers face as a consequence of climate change.
Department of Homeland Security		
Office of Health Affairs	Works with communities nationwide to prepare for and respond to emergencies, including by assisting officials in understanding health risks during emergencies.	• Developed a Community Health Resilience Initiative Guide and Toolset, which provides local decision makers with information needed to strengthen community resilience from a variety of impacts, including health impacts related to climate change. • Reviews climate change impacts to its field-based departmental workforce, such as those working for U.S. Customs and Border Protection. • Oversees the National Biosurveillance Integration Center, an interagency center that tracks patterns of disease, disease vectors, food- and water- borne pathogens, among other factors that could influence public health.
Federal Emergency Management Agency	Works to enhance the nation's capability to prepare for, protect against, respond to, recover from, and mitigate all hazards, including by providing data and tools.	• Provides data and tools such as the National Flood Hazard Layer, which allows users to identify base flood elevation and other data that can be used by local decision makers to identify vulnerable populations. • Provides awards to state, local, tribal, and territorial governments to enhance their ability to prevent, respond to, mitigate, and recover from all hazards, including those related to climate change.

Department and component agency or office	Summary of work related to climate change and health	Examples of activities
Department of the Interior		
U.S. Geological Survey	Provides scientific information to describe and understand the Earth and to minimize loss of life and property from natural disasters, among other functions.	• Through its Climate Science Centers, studies the impact of climate change on fish, wildlife, and their habitats to help decision makers address the impacts of climate change, some of which can impact human health and well-being. • Developed the Coastal Vulnerability Index, which provides a preliminary overview, at a national scale, of the relative vulnerability of the nation's coast to sea-level rise, a climate change impact that may affect public health, including mental health in impacted communities. • Provides the Disease Maps Web page, which includes seasonal tracking of seven vector-borne diseases in the United States and territories, including West Nile virus and dengue, which may be impacted by climate change.
Bureau of Indian Affairs	Provides awards for some tribes to conduct climate change adaptation planning, training, and capacity building, which could help these tribes address related risks to public health.	• Provided an award to a regional tribal community partnership in southeast Alaska to monitor beaches and shellfish for toxins from harmful algal blooms.
Office of Insular Affairs	Coordinates federal policy in the territories of American Samoa, Guam, the U.S. Virgin Islands and the Commonwealth of the Northern Mariana Islands.	• Hosted its first stakeholder meeting on climate change in June 2015 for federal officials and leaders from the territories that the office engages with to discuss climate change adaptation efforts in those territories.
Environmental Protection Agency		
	Collects and disseminates environmental data, studies the impact of environmental exposures on human health, and provides decision support resources to state and local decision makers that can assist them in preparing for the impacts of climate change, among other functions.	• Developed a community edition of its Benefits Mapping and Analysis Program, an open-source computer program that helps users estimate the health impacts and economic value of changes in air quality. • Provides awards for Pediatric Environmental Health Specialty Units to educate health professionals and others about environmental health risks, including some that may be exacerbated by climate change. • Provides awards to states and tribes for drinking water and wastewater system projects that can help address some risks from climate change, such as from altered precipitation and runoff patterns. • Worked with the Institute for Tribal Environmental Professionals at Northern Arizona University to develop a national training program and online resources to assist tribal leaders in developing adaptation plans to prepare for the impacts of climate change, including human health impacts.
National Aeronautics and Space Administration (NASA)		
	Through its Applied Sciences Program, partners with public and private organizations on ways to apply agency data in their decision-making activities.	• Collects and analyzes remote sensing data, including data on air quality, extreme weather, biodiversity, and changes in land cover, which may be used by decision makers to assess climate change impacts on health. • Working with NOAA's National Weather Service, provided awards for projects in three U.S. cities to develop more effective heat advisory thresholds by using NASA land surface data to identify extreme hotspots and data about morbidity and mortality to identify neighborhoods at the highest risk for health effects from heat waves.

Table 5. (Continued)

Department and component agency or office	Summary of work related to climate change and health	Examples of activities
National Science Foundation		
	Funds a wide array of scientific research that could be useful in understanding climate change and, less directly, its impacts on human health.	• Provided awards for research on climate change and oceans, such as impacts on rising ocean temperatures and increased ocean acidity resulting from absorption of atmospheric emissions, which alter the characteristics of the most fundamental organisms of the ocean food chain. • Provided awards for research on how people make decisions, including those related to climate change, during times of uncertainty. • Provided awards for research on the ecology and evolution of infectious disease, including research related to the spread of Lyme disease in ticks.
Smithsonian Institution		
	Provides knowledge about nature and culture through research, collections, exhibitions, and education efforts, among other functions.	• Hosted a 1-day symposium in October 2014 on climate and health, among other topics, which included a panel on health in a changing climate. • Planned and organized a June 2014 webinar on food security in the Arctic, which included a discussion of challenges to food security posed by climate change.
U.S. Department of Agriculture		
Office of the Chief Economist	Coordinates the department's responses to climate change.	• Initiated an evaluation of possible changes to the food system, and thus to food security outcomes, as a result of changes in weather and climate, both historically and over the next 25 to 100 years.
Agricultural Research Service	Conducts research on agricultural problems of high national priority, and provides information to ensure high-quality, safe food and assess the nutritional needs of Americans, among other functions.	• Helped support research on improving models for evaluating the effects of climate change and adaptation on crop production, a topic that could be useful for understanding how climate change may affect food availability and prices, which may impact human health.
Animal and Plant Health Inspection Service	Administers the Animal Welfare Act and carries out wildlife damage management activities, among other functions.	• During emergencies, including any that may be caused or exacerbated by climate change, supports the evacuation of people with their pets, which officials told us was essential because some people will not evacuate without their pets.
Economic Research Service	Conducts economic research and provides information related to issues including agriculture, food, and the environment.	• Issues a Cost Estimates of Food-borne Illnesses data product, which includes data about the costs of major food-borne illnesses in the United States, including for illnesses that may increase as a result of climate change.
Forest Service	Aims to achieve quality land management by, among other things, protecting and managing national forests and helping states and communities to use their forests wisely.	• Provides an online climate change resource center for land managers and decision makers interested in learning more about climate change and what they can do. The site focuses on forests and other ecosystems, but includes some information related to human health.
National Institute of Food and Agriculture	Provides leadership and funding for programs that advance agriculture-related sciences.	• Provided awards for basic and applied research related to climate change, such as research on how climate change may affect the water quality functions of on-site wastewater treatment systems, and identifies climate change as a priority research area for research it manages.

Department and component agency or office	Summary of work related to climate change and health	Examples of activities
Natural Resources Conservation Service	Provides farmers and ranchers with financial and technical assistance to voluntarily enact conservation measures.	Through its National Water and Climate Center, monitors and provides information on droughts and water supplies critical for both agricultural and urban uses.
U.S. Global Change Research Program		
	Aims to build a knowledge base that informs human responses to climate and global change through coordinated and integrated federal programs of research, education, communication, and decision support resources.	Included a health chapter in its third National Climate Assessment, published in May 2014, and, through its Interagency Crosscutting Group on Climate Change and Human Health, initiated a scientific assessment of the human health impacts of climate change, a draft of which was released for public comment in April 2015.
Council on Environmental Quality		
	Coordinates federal environmental efforts and works closely with agencies and other White House offices in the development of environmental policies and initiatives.	- Co-chaired the State, Local, and Tribal Leaders Task Force on Climate Preparedness and Resilience, which published a final report in November 2014 that included recommendations for federal action on climate change and public health. - Reviewed federal agencies' climate change adaptation plans, which include information on how climate change could impact the health and well-being of their employees.

APPENDIX VI: EXAMPLES OF ACTIVITIES CONDUCTED BY Awardees of CDC's Climate Ready States and Cities Initiative

State and local health officials from the 16 state and two local health departments receiving awards through the Center for Disease Control and Prevention's (CDC) Climate Ready States and Cities Initiative told us that they have conducted a variety of activities to address and plan for the risks that climate change poses to public health. These activities support awardees' efforts to implement CDC's Building Resilience Against Climate Effects (BRACE) framework—a five-step risk management approach intended to help public health departments identify and prepare for the public health impacts of climate change by, among other things, incorporating atmospheric data and climate projections into public health planning. Examples of these activities include the following:

- Developing community vulnerability and resilience indicators.** Awardees have developed indicators to measure community vulnerability and resilience. Florida, for example, developed indicators to identify relationships between measures of social and medical vulnerabilities, such as age and access to health care facilities, with risks to climate-related hazards in the state including hurricane winds and wildland fire.⁹⁷ Officials from the city of San Francisco also created a series of community resilience indicators to provide quantitative measurements of vulnerability to climate change stressors in the city, by neighborhood.⁹⁸ Indicators were developed in a variety of categories, including in areas related to the environment, health, housing, and the

economy, and then mapped by census tract. See figure 4 for an example of a map developed to display areas of vulnerability to extreme heat based on the percentage of buildings with air-conditioning.

Source: San Francisco Department of Public Health (image). | GAO-16-122

Note: According to the San Francisco Department of Public Health, in housing stock without other forms of ventilation, air conditioning can prevent the health effects of extreme heat. Residents in buildings with centralized air conditioning units are at far lesser risk of heat stress. In multiunit buildings without centralized air, personal units often place the financial burden of cooling on low-income residents and incentivize disuse.

Figure 4. Example of a community resilience map illustrating vulnerabilities to extreme heat in San Francisco.

- **Enhancing surveillance.** Some awardees described taking efforts to enhance the amount and type of surveillance data they collect. For example, Vermont developed Web-based tools for the public to report surveillance information related to the spread of ticks and algal blooms. Specifically, through its interactive tick tracker, the public can share information about where and what kinds of ticks have been observed, in order to better prevent the occurrence of tick bites in others.
- **Incorporating climate change into emergency preparedness planning.** Awardees told us that they have incorporated climate change considerations into emergency preparedness planning, such as by developing plans for hazards related to climate change, which can include heat waves or other extreme weather events. For example, Arizona created outreach materials on extreme heat and flooding emergencies to support local health departments. In addition, the state provided technical assistance

to a county to create an extreme weather response plan, which included responding to extreme heat events. Illinois also incorporated climate change considerations into emergency preparedness planning by requiring that local health departments demonstrate that they are planning for an increase in the frequency and severity of extreme weather events in order to obtain public health emergency preparedness funding from the state.

- **Developing communication materials.** Awardees have developed communication materials to share information on the risks that climate change poses to public health in their jurisdictions, such as through websites for their Climate and Health programs. Officials from one county receiving funds through California's Climate and Health Program told us that its jurisdiction developed a climate change communications campaign for the purpose of educating health department staff and the community. As part of this effort, county health officials developed public service announcements to air on county-based radio stations—in English and in Spanish—that explain climate change and health-related topics, such as food, transportation, and energy.
- **Engaging communities.** Awardees described efforts to engage communities, particularly those vulnerable to the risks that climate change poses to public health. For example, officials from New York City described conducting focus groups with seniors and their caregivers to obtain their perspectives on awareness of heat warnings, prevention behaviors, and air-conditioning prevalence and use during heat waves. Officials from San Francisco also reported holding town hall style meetings with community groups from selected neighborhoods to discuss issues related to climate and health, including heat, sea level rise, and vulnerable populations in these specific areas.
- **Partnering with academic institutions.** Awardees reported forming partnerships with academic institutions to, among other things, develop vulnerability assessments and translate climate science information. In some cases, these partnerships were the result of the health department providing a small amount of funding to the university to conduct these assessments, according to officials. For example, officials from Maryland told us that they are collaborating with researchers at the University of Maryland to develop vulnerability assessments and develop county-level projections of the burden of disease from climate change on particular health impacts, such as asthma and waterborne illness. Maryland officials noted the importance of partnering with the University to conduct this work, given the limited resources of the health department and difficulties associated with hiring staff to conduct this assessment.
- **Collaborating with other state or local entities.** Awardees have developed relationships with other state or local departments in conducting activities related to addressing and preparing for the risks that climate change poses to public health. Awardees mentioned that these partnerships help others gain a better perspective of the health impacts of climate change, which will help them to consider health impacts as they make decisions in their respective fields. Awardees also noted that they have shared information with partners or worked collaboratively on projects. For example, officials from the Michigan Department of Community Health reported partnering with the state's Department of Environmental Quality to receive data on topics related to air or water quality. Some awardees also noted the importance of

developing partnerships with their state climatologist to provide their health departments with technical assistance in interpreting climate data.

APPENDIX VII: ACTIVITIES OF OTHER SELECTED STATE AND LOCAL HEALTH DEPARTMENTS RELATED TO PREPARING FOR THE PUBLIC HEALTH IMPACTS OF CLIMATE CHANGE

Officials from some of 13 state and local health departments that we interviewed that have not received an award through the Centers for Disease Control and Prevention's (CDC) Climate Ready States and Cities Initiative have conducted some activities related to addressing and planning for the risks that climate change poses to public health, to the extent that they have resources available.⁹⁹ Some of these state and local health department officials began working on this issue as a result of receiving leadership direction to do so, whereas others did so in the absence of leadership direction, because they believe it is an important issue or because they have identified the need to acknowledge the issue based on knowledge of climate change risks in their jurisdictions.

While some departments have conducted work in this area, others did not have the resources to begin or sustain a robust level of activity. State and local health officials told us that they have few staff to work on such activities, and that those staff also have other assignments and responsibilities. Efforts related to preparing for climate change risks to human health are often conducted in an ad hoc manner compared to those receiving awards through CDC's Climate Ready States and Cities Initiative. Some officials also told us that they have partnered with or received support from academic institutions and nonprofit organizations, which has been beneficial in beginning their work in this area since they have few resources to devote to this issue within their health departments.

State and local health departments not receiving the award that have begun planning for the risks that climate change poses to public health have undertaken activities such as conducting research on health impacts associated with climate change, such as heat-related illness or asthma, participating in workgroups, holding forums to raise awareness, and producing reports. Among the state and local health departments that we interviewed, Alaska and Washington were among those not receiving the CDC initiative award that had undertaken a number of activities directly related to preparing for the public health impacts of climate change.

- **Alaska.** Officials from the Alaska Department of Health and the Alaska Native Tribal Health Consortium—a nonprofit tribal health organization—told us that they have engaged in a number of activities to address and plan for the risks that climate change poses to public health, given that Alaska residents are already seeing climate change impacts to their health and livelihoods. The state's Department of Health is in the early stages of developing a health impact assessment that seeks to identify the potential costs of climate change to health, ways in which to minimize adverse health effects, and ways in which to maximize potential health benefits. The results of this assessment will serve as a baseline for future climate change planning and preparedness activities in the state. Officials from the Department of Health were

also involved in studying an outbreak of *vibrio parahaemolyticus* in July 2004, due, in part, to rising ocean temperatures.¹⁰⁰ The Alaska Native Tribal Health Consortium has also conducted activities related to climate change and health. Through an award provided by HHS's Indian Health Service, the center has conducted assessments to understand the broad range of community impacts from climate change, including changes in disease, mental health, food and water security, and infrastructure. The center is integrating the results of these assessments into construction design, operations, and maintenance considerations for specific health facility improvements, such as new filtration systems for water treatment plants. The center also developed a Local Environmental Observers network, consisting of tribal environmental, natural resources, and health professionals, to enhance monitoring of unusual events that are climate change-related or climate-sensitive. Observations are mapped on a Google maps platform and are communicated through an electronic newsletter to provide information to decision makers on current risks.¹⁰¹

- **Washington.** The Washington State Department of Health has recently started to engage in activities related to climate change and health at the direction of its Secretary of Health, who identified climate change as a priority issue. The department is working to identify how to measure and track the impacts of climate change, particularly in the areas of food, water, and air quality, through its Washington Tracking Network, which is funded by CDC's Environmental Public Health Tracking Network. The department also conducted a survey to characterize local health jurisdiction's perceptions, activities, and needs related to climate change, and compared the results to similar surveys of local health departments on this topic.

APPENDIX VIII: SUMMARY OF HEALTH-RELATED RECOMMENDATIONS MADE BY THE PRESIDENT'S TASK FORCE ON CLIMATE PREPAREDNESS AND RESILIENCE

In November 2013, the President issued Executive Order 13653, *Preparing the United States for the Impacts of Climate Change*, which, among other things, established the State, Local, and Tribal Leaders Task Force on Climate Preparedness and Resilience. The mission of the task force was to provide recommendations to the President and interagency council on how the federal government could, among other things, support state, local, and tribal preparedness for and resilience to climate change.

The task force issued a report to the President in November 2014, noting that the federal government has an essential and unique role to play in preparing for and responding to climate change impacts.¹⁰² Its report includes 35 recommendations to the President across seven themes, and it also listed suggested actions that federal agencies could take to implement the recommendations. The themes addressed in the report are (1) building resilient communities, (2) improving resilience in the nation's infrastructure, (3) ensuring resilience of natural resources, (4) preserving human health and supporting resilient populations, (5) supporting climate-smart hazard mitigation and disaster preparedness and recovery, (6) understanding and acting on the economics of resilience, and (7) building capacity. Table 6

summarizes selected health-related recommendations and suggested actions listed across various themes of the report.

Table 6. Summary of selected health-related recommendations and suggested actions from the President’s state, local and tribal leaders task force report on climate preparedness and resilience

Theme	Recommendation	Examples of suggested actions to address the recommendation
Preserving human health and supporting resilient populations		
	Address the needs of vulnerable populations	• Develop guidance and tools to identify those most at risk the effects of climate change. • Ensure that federal programs that serve vulnerable populations (for example, housing and senior assistance programs) evaluate how climate change will impact needs and service delivery.
	Improve capacity to protect public health	• Expand and build on the Centers for Disease Control and Prevention’s (CDC) Climate-Ready States and Cities Initiative, to include mechanisms for grantees to share their experience and best practices with nongrantees, including all local governments. • Encourage recipients of CDC’s Public Health Emergency Preparedness funding to consider climate change impacts when developing their required vulnerability assessments. • Develop climate-sensitive health tracking and surveillance tools. • Improve awareness of mental health impacts associated with climate change impacts, including by incorporating such impacts in preparedness and response planning.
	Assist communities in building food system security.	• U.S. Department of Agriculture should work with the Department of Health and Human Services and others to support research on climate change-related risks to food supply chains.
	Improve disaster preparedness for communities most at-risk.	• Provide enhanced access to predisaster training on federal response and recovery programs. • Develop health-sensitive extreme weather event warning systems that enhance response activities for at-risk populations.
	Explore the federal role in addressing climate change-related displacement.	• Establish a framework for responding to climate-related displacement.
Building capacity for resilience		
	Increase climate literacy and public awareness.	• Ensure that senior federal health officials such as the U.S. Surgeon General and the Director of CDC draw attention to the public health impacts of climate change. • Coordinate federal communications on climate change to develop clear, consistent, and unified messages, including on the impacts of climate change to human health, and ensure that communications tools are provided to state and local governments.
Ensuring the resilience of natural resources		
	Combat the spread of invasive species, pests, and diseases.	• Increase regional monitoring efforts, including by enhancing related research, identification, interagency coordination, and education efforts.

Source: President’s State, Local and Tribal Leader’s Task Force Report on Climate Preparedness and Resilience, Recommendations to the President (Washington, D.C.: Nov. 17, 2014). | GAO-16-122.

The task force also developed five overarching principles for all federal agencies to consider as a means to advance climate preparedness and resiliency. These include:

1. Require consideration of climate-related risks and vulnerabilities as part of all federal policies, practices, investments, and regulatory or other programs.
2. Maximize opportunities to take actions that have dual benefits of increasing community resilience and reducing greenhouse gas emissions.
3. Strengthen coordination and partnerships among federal agencies, and across federal, state, local, and tribal jurisdictions and economic sectors.
4. Provide actionable data and information on climate change impacts and related tools and assistance to support decision making.
5. Consult and cooperate with tribes and indigenous communities on all aspects of federal climate preparedness and resilience efforts, and encourage states and local communities to do the same.

END NOTES

¹ National Research Council, *America's Climate Choices: Panel on Adapting to the Impacts of Climate Change, Adapting to the Impacts of Climate Change* (Washington, D.C.: 2010); Jerry M. Melillo, Terese (T.C.) Richmond, and Gary W. Yohe, eds., *Climate Change Impacts in the United States: The Third National Climate Assessment*, U.S. Global Change Research Program (Washington, D.C.: May 2014); and K.R. Smith, K.R., et al., *Human Health: Impacts, Adaptation, and Co-Benefits in Climate Change 2014: Impacts, Adaptation, and Vulnerability. Part A: Global and Sectoral Aspects. Contribution of Working Group II to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change* (Cambridge, United Kingdom: 2014). The National Research Council is the principal operating agency of the National Academy of Sciences and the National Academy of Engineering. USGCRP coordinates and integrates the activities of 13 federal agencies that conduct research on changes in the global environment and their implications for the United States. USGCRP began as a presidential initiative in 1989 and was codified in the Global Change Research Act of 1990 (Pub. L. No. 101-606, § 103 (1990)). The act requires USGCRP to periodically prepare a scientific assessment—known as the National Climate Assessment—which is an important resource for understanding and communicating climate change science and impacts in the United States. The Intergovernmental Panel on Climate Change is a scientific body under the auspices of the United Nations that was designed to assess the scientific, environmental, and socioeconomic aspects of climate change.

² World Health Organization, *Quantitative Risk Assessment of the Effects of Climate Change on Selected Causes of Death, 2030s and 2050s* (Geneva, Switzerland: 2014). The World Health Organization directs and coordinates international health within the United Nations system. In this study, WHO modeling and simulation results estimate 240,000 additional deaths worldwide in 2030 due to the health effects of a changing climate.

³ While climate change poses health risks worldwide, this report focuses on the risks that climate change poses to human health within the United States.

⁴ In 2014, the federal government spent \$815 billion on Medicare, Medicaid, and the Children's Health Insurance Program, which provide coverage for the elderly, low-income individuals, and children, respectively. Office of Management and Budget, *Analytical Perspectives, Budget of the United States Government, Fiscal Year 2016* (Washington, D.C.: Feb. 2, 2015).

⁵ During this 16-day heat wave, more than 10 times the number of hospitalizations for heat-related illnesses occurred statewide, and more than 23 times the number of emergency department visits for heat-related illnesses occurred in the most affected region, as had been recorded in 6 days prior and 10 days following the event. One study estimated that this heat wave resulted in nearly \$180 million in additional health care costs. K. Knowlton, et al., "The 2006 California Heat Wave: Impacts of Hospitalizations and Emergency Department Visits," *Environmental Health Perspectives* 117 (2009) and K. Knowlton, et al., "Six Climate Change-Related Events in the United States Accounted for About \$14 Billion in Lost Lives and Health Costs," *Health Affairs* 30, no. 11 (2011).

⁶ GAO, *High-Risk Series: An Update*, GAO-13-283 (Washington, D.C.: Feb. 14, 2013).

⁷ Disease surveillance is the process of reporting, collecting, analyzing, and exchanging information related to cases of infectious diseases. For more information on state and local public health agency activities related to

climate change, see H. Frumkin, et al., “Climate Change: The Public Health Response,” *American Journal of Public Health* 98, no. 3 (2008).

- ⁸ The 2014 assessment summarizes the impacts of climate change on the United States, now and in the future. A team of several hundred experts guided by a 60-member Federal Advisory Committee produced the report, which was extensively reviewed by the public and experts, including federal agencies and a panel of the National Academy of Sciences. The 2010 report, developed by an ad hoc interagency working group on climate change and health, summarizes research needs on the human health effects of climate change. See, Interagency Working Group on Climate Change and Health, *A Human Health Perspective on Climate Change: A Report Outlining the Research Needs on the Human Health Effects of Climate Change*, National Institute of Environmental Health Sciences (Research Triangle Park, N.C.: April 2010).
- ⁹ Specifically, we interviewed officials from 26 federal agencies: Department of Commerce’s National Oceanic and Atmospheric Administration; Department of Defense’s Defense Health Agency, Department of Health and Human Services’ Assistant Secretary for Preparedness and Response, Centers for Disease Control and Prevention, Indian Health Service, National Institutes of Health, and Office of the Assistant Secretary for Health; the Department of Homeland Security’s Federal Emergency Management Agency and Office of Health Affairs; Department of the Interior’s Bureau of Indian Affairs, Office of Insular Affairs, and U.S. Geological Survey; Environmental Protection Agency; National Aeronautic and Space Administration; National Science Foundation, and the U.S. Department of Agriculture’s Agricultural Marketing Service, Animal and Plant Health Inspection Service, Agricultural Research Service, National Institute of Food and Agriculture, Economic Research Service, Forest Service, Natural Resources Conservation Service, and the Office of the Chief Economist, USGCRP, and the Council on Environmental Quality. These agencies include those that participate in USGCRP’s Interagency Crosscutting Group on Climate Change and Human Health and whose focus is on understanding risks to populations within the United States.
- ¹⁰ The American Public Health Association is a national nonprofit organization representing public health officials, whose mission is to improve the health of the public and achieve equity in health status.
- ¹¹ The Georgetown Climate Center, a nonpartisan organization of Georgetown University Law Center, seeks to advance policies that reduce greenhouse gas emissions and help communities adapt to climate change.
- ¹² We did not review governmentwide data on funding for such research because such data were not readily available.
- ¹³ In identifying these examples, we did not limit the scope of our work to a specific time period.
- ¹⁴ Adaptation refers to adjustments to natural or human systems that are made in response to actual or expected climate changes. While our report focuses on activities taken to adapt to the potential health impacts of climate change, federal agencies and others are also involved in climate change mitigation—that is, taking actions to limit the magnitude or rate of climate change. EPA recently reported on the physical and monetary benefits in the United States of global mitigation, including that it is projected to reduce the impact of climate change on air quality and the corresponding adverse health effects related to air pollution, avoiding 57,000 premature deaths in 2100. EPA, *Climate Change in the United States: Benefits of Global Action* (Washington, D.C.: June 2015).
- ¹⁵ ASTHO is a national nonprofit organization representing public health agencies in the United States, the U.S. Territories, and the District of Columbia, and over 100,000 public health professionals these agencies employ. ASTHO’s primary function is to track, evaluate, and advise members on the impact and formation of public or private health policy that may affect them and to provide them with guidance and technical assistance on improving the nation’s health.
- ¹⁶ NACCHO’s mission is to be a leader, partner, catalyst, and voice for the 2,800 local health departments across the United States in order to ensure the conditions that promote health and equity, combat disease, and improve the quality and length of all lives.
- ¹⁷ We conducted one small group discussion session in person with state health department officials during the American Public Health Association’s annual meeting, and we conducted three additional sessions by teleconference with state and local health department officials, to capture the perspectives of those who were unable to attend our in-person session. In total, we conducted three sessions with state health department officials and one session with local health department officials. In addition to working with ASTHO and NACCHO to identify potential participants, we also conducted some targeted recruitment of officials from state and local health departments receiving awards through CDC’s Climate Ready States and Cities Initiative to include these jurisdictions in our small group discussion sessions.
- ¹⁸ We interviewed officials from all 16 states and two cities that were awarded funding through CDC’s Climate Ready States and Cities Initiative—Arizona, California, Florida, Illinois, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Hampshire, New York, North Carolina, Oregon, Rhode Island, Vermont, Wisconsin, as well as New York City and San Francisco. In addition, we interviewed officials from seven local health departments located in states that received the CDC award, including Baltimore (MD), Benton County (OR), Multnomah County (OR), San Diego County (CA), San Luis Obispo County (CA), Washington County (MD), and Wicomico County (MD). We also interviewed officials from five other state and eight other local health departments: Alaska, Hawaii, Louisiana, Utah, and Washington, as well as Columbus (OH),

Dallas County (TX), Houston (TX), Portsmouth (VA), Salt Lake County (UT), Shelby County (TN), Summit County (OH), and Toledo (OH). We interviewed officials from a few state and local health departments twice, through different approaches.

- ¹⁹ The results from our analysis identify the three themes that were commonly reported by a diverse group of state and local health departments. These results are not generalizable to other state and local health departments and do not necessarily include all challenges that public health departments may face.
- ²⁰ National Research Council, *America's Climate Choices: Panel on Adapting to the Impacts of Climate Change, Adapting to the Impacts of Climate Change* (Washington, D.C.: 2010); and Melillo, Richmond, and Yohe, eds., *Climate Change Impacts in the United States: The Third National Climate Assessment*.
- ²¹ Because of greenhouse gases already in the atmosphere, another 0.5 degree Fahrenheit increase would occur even if all emissions from human activities were suddenly stopped, according to USGCRP's third NCA.
- ²² Chikungunya is a viral disease spread to people by the bite of infected mosquitoes. According to CDC, the first locally acquired cases of chikungunya were reported in Florida in 2014. Dengue is caused by any one of four related viruses transmitted by mosquitoes. According to CDC, dengue is endemic to Puerto Rico and the Pacific Islands, and occurs only infrequently in the United States. Lyme disease is a bacterial disease that is transmitted to humans through the bite of infected blacklegged ticks. Most Lyme disease cases reported to CDC through national surveillance are concentrated heavily in the Northeast and upper Midwest. West Nile virus is most commonly transmitted to humans by mosquitoes. According to CDC, the virus has been detected in all of the 48 contiguous United States, but not in Hawaii or Alaska.
- ²³ For example, Native American communities' vulnerabilities to climate change impacts are exacerbated by poor socioeconomic conditions, according to USGCRP's third NCA.
- ²⁴ EPA, *Climate Change and Children's Health* (Washington, D.C.: December 2009). In a prior report, we noted that as children's bodies are still developing, they can be more vulnerable than adults to certain environmental hazards, including air pollutants. See GAO, *Environmental Health: EPA Has Made Substantial Progress but Could Improve Processes for Considering Children's Health*, GAO-13-254 (Washington, D.C.: Aug. 12, 2013).
- ²⁵ Each of the 50 states has a state health department and according to NACCHO, about 2,800 local health departments exist across the nation, including those that function at the city, county, or multicounty level.
- ²⁶ Decision support resources—including tools and decision-making frameworks—can help decision makers to understand and apply scientific information to a particular scenario, and identify and assess the costs and benefits of taking various actions, among other things.
- ²⁷ Implementing resilience measures creates additional up-front costs but could also confer benefits, such as a reduction in future damages from climate-related events. See GAO, *Budget Issues: Opportunities to Reduce Federal Fiscal Exposures Through Greater Resilience to Climate Change and Extreme Weather*, GAO-14-504T (Washington, D.C.: July 29, 2014).
- ²⁸ Executive Order 13514, *Federal Leadership in Environmental, Energy, and Economic Performance* (Oct. 5, 2009). This Executive Order was revoked by Executive Order 13693 on March 19, 2015; however, an Executive Order issued in 2013 directed agencies to continue developing, updating, and implementing agency adaptation plans. Executive Order 13653, *Preparing the United States for the Impacts of Climate Change* (Nov. 1, 2013).
- ²⁹ The Council on Environmental Quality coordinates federal environmental efforts and works with agencies and other White House offices in the development of environmental policies and initiatives.
- ³⁰ *Instructions for Implementing Climate Change Adaptation Planning in Accordance with Executive Order 13514 "Federal Leadership in Environmental, Energy, and Economic Performance,"* (Mar. 4, 2011).
- ³¹ *The President's Climate Action Plan* (June 2013).
- ³² Executive Order 13653, *Preparing the United States for the Impacts of Climate Change* (Nov. 1, 2013).
- ³³ The task force consisted of 26 governors, mayors, county officials, and tribal leaders from across the United States, and was co-chaired by the Chair of the White House Council on Environmental Quality and the Director of the White House Office of Intergovernmental Affairs.
- ³⁴ The recording of the summit is available online at [https:// www.whitehouse.gov/ blog/ 2015/ 06/18/public-health-climate-summit](https://www.whitehouse.gov/blog/2015/06/18/public-health-climate-summit).
- ³⁵ Additional federal agencies participating in the CCHHG are the U.S. Departments of Agriculture, Defense, Interior, State; EPA; National Aeronautics and Space Administration; the Smithsonian Institution; and the U.S. Agency for International Development.
- ³⁶ Examples of funded projects include a study examining the health risks of heat and air pollution, and a study examining the impacts of extreme heat on inner-city minority children with asthma and older adults with chronic obstructive pulmonary disease.
- ³⁷ The funding opportunity for exploratory research was issued in 2010 by National Institute of Environmental Health Sciences with the participation of the Fogarty International Center, National Cancer Institute, National Center on Minority Health and Health Disparities, National Heart, Lung, and Blood Institute, National Institute on Aging, National Institute on Biomedical Imaging and Bioengineering, National Institute of Child

Health and Human Development, National Institute of General Medical Sciences, National Library of Medicine, and the Office of Behavioral and Social Sciences Research.

- ³⁸ NIH reported awarding a total of about \$28 million for research on the health impacts of climate change for fiscal year 2011 through fiscal year 2014, which includes nearly all of the projects funded through the NIH solicitation for research proposals, as well as other unsolicited research. For this period, NIH also reported awarding about \$579 million for research on exposures or conditions that are related to climate, such as research on melanoma. Because these categories are not mutually exclusive, funding for some research is included in both groups.
- ³⁹ An indicator is an observation or calculation that allows scientists, analysts, decision makers, and others to track environmental trends, understand key factors that influence the environment, and identify effects on ecosystems and society.

- ⁵⁵ EPA, "Speeches by Date," Administrator Gina McCarthy, *Keynote Remarks at the University of Michigan Environmental Law and Public Health Conference, As Prepared*, <http://yosemite.epa.gov/opa/admpress.nsf/8d49f7ad4bbcf4ef852573590040b7f6/ac6b9218ba9e1e2885257bf2005a41cb1?OpenDocument> (accessed April 2, 2015).
- ⁵⁶ In conducting this work, we spoke with officials from all 18 health departments receiving the award—who we refer to as awardees—about the activities they have conducted related to climate change and public health.
- ⁵⁷ In fiscal year 2014, individual awards ranged from \$173,000 to \$250,000. According to CDC officials, funding for awardees varies by award cycle, as awardees are funded under two cooperative agreement mechanisms—a fiscal year 2012 agreement funded 8 awardees for 4 years, through fiscal year 2016, and a fiscal year 2013 agreement funded 10 awardees for 3 years, through fiscal year 2016.
- ⁵⁸ Officials from CDC's Climate and Health Program told us that they make information about the BRACE framework available on the program's website and through a peer-reviewed journal article. See <http://www.cdc.gov/climateandhealth/brace.htm> and G.D. Marinucci, et al., "Building Resilience against Climate Effects—A Novel Framework to Facilitate Climate Readiness in Public Health Agencies," *International Journal of Environmental Research and Public Health* 11, no.6 (2014).

- ⁵⁹ See Centers for Disease Control and Prevention, *Climate Models and the Use of Climate Projections: A Brief Overview for Health Departments* (2014), and Centers for Disease Control and Prevention, *Assessing Health Vulnerability to Climate Change: A Guide for Health Departments* (2014).
- ⁶⁰ CDC also makes some of these resources available on its Climate and Health Program website, see http://www.cdc.gov/climateandhealth/site_resources.htm.
- ⁶¹ According to CDC officials, as of May 2015, there are five communities of practice, related to vector-borne diseases, water-borne diseases, conducting vulnerability assessments, developing disease projections, and developing evaluation plans.
- ⁶² According to officials from the New York City Department of Health and Mental Hygiene, a Heat Health Watch and Warning System uses daily forecasts of the dominant local weather pattern to calculate predicted excess deaths from periods of excessive heat based on location-specific historical data.
- ⁶³ CDC's National Environmental Public Health Tracking Network Reporting Tool is available online at <http://ephrtracking.cdc.gov/QueryPanel/EPHTNQuery/EPHTQuery.html?c=-1&i=-1&m=-1>.
- ⁶⁴ Specifically, these indicators use historical weather and health data to identify extreme temperatures, extreme heat days and events, deaths that might be related to heat, and conditions that make people vulnerable to heat. They also project future extreme heat events to help estimate the burden of heat-related illness in the next century. Data for these indicators and associated measures are available at the national, state, or county level, depending on the indicator and measure. According to CDC officials, the program is planning to adopt additional climate change-related indicators in the future.
- ⁶⁵ The program made 26 awards to state and local programs in fiscal year 2014 for a 3- year award cycle. Thirteen of the 18 Climate Ready States and Cities Initiative awardees also received National Environmental Public Health Tracking Network awards in fiscal year 2015.
- ⁶⁶ CDC's Public Health Emergency Preparedness program makes awards to public health departments in all 50 states, four major metropolitan areas (Chicago, Los Angeles County, New York City and Washington, D.C.), and eight U.S. territories and freely associated states (American Samoa, Guam, U.S. Virgin Islands, Northern Mariana Islands, Puerto Rico, Federated States of Micronesia, Republic of the Marshall Islands, and Republic of Palau).
- ⁶⁷ Specifically, awardees are required to build and sustain their public health preparedness capabilities according to standards developed by CDC. Awardees are also required to review their preparedness status annually by using information from a variety of sources, such as jurisdictional risk assessments.
- ⁶⁸ Through its State-Based Occupational Health and Safety Surveillance program, the National Institute for Occupational Safety and Health provides awards to 23 states to collect data on occupational safety and health hazards and effects, identify new sources of occupational safety and health data, conduct surveillance, interpret findings, and develop or recommend related interventions. According to officials from the National Institute for Occupational Safety and Health, the program awarded nearly \$6.5 million to state health departments in fiscal year 2014, with individual awards ranging from about \$100,000 to nearly \$900,000. Twelve of the 18 Climate Ready States and Cities Initiative awardees were also awardees of the State-Based Occupational Health and Safety Surveillance program in fiscal year 2014.
- ⁶⁹ NOAA's Regional Integrated Sciences and Assessment teams are university-based research partnerships that help build the nation's capacity to prepare for and adapt to climate variability and change.
- ⁷⁰ GAO, *Climate Change Adaptation: Strategic Federal Planning Could Help Government Officials Make More Informed Decisions*, GAO-10-113 (Washington, D.C.: Oct. 7, 2009).
- ⁷¹ Some awardees of CDC's Climate Ready States and Cities Initiative told us that they have begun to provide briefings or trainings on climate and health issues for departmental staff.
- ⁷² National Association of County and City Health Officials. *Are We Ready? Report 2 Preparing for the Public Health Challenges of Climate Change* (Washington, D.C.: 2014).
- ⁷³ According to our review of this analysis, 22 states have finalized climate change adaptation plans or have such planning underway. See Georgetown Climate Center, *State and Local Adaptation Plans*, <http://www.georgetownclimate.org/adaptation/state-and-local-plans> (accessed May 15, 2015).
- ⁷⁴ See American Public Health Association, *Climate Change Is a Public Health Issue* (Washington, D.C.: 2008), and American Public Health Association, *Climate Change: Our Health in the Balance. National Public Health Week 2008 Partner Toolkit* (Washington, D.C.: 2008).
- ⁷⁵ In our previous work on climate change adaptation, we also found that climate change adaptation is a complicated issue to communicate with the public because the impacts vary by location and may occur well into the future. See GAO-10-113.
- ⁷⁶ While Ebola did not present a significant risk to the U.S. public, two imported cases, and two locally acquired cases in health care workers were reported in the United States. According to ASTHO and NACCHO, state and local health departments worked to enhance preparedness in their jurisdictions, including by collaborating with health care providers in their jurisdictions to ensure they had adequate information on screening, isolating, and diagnosing potential patients, reiterating the importance of infection control procedures for health care givers, working with laboratories to provide guidance on safe handling of specimens, and creating and providing timely and consistent messages for the public about the disease.

- ⁷⁷ President's State, Local, and Tribal Leaders Task Force on Climate Preparedness and Resilience, *Recommendations to the President* (Washington, D.C.: Nov. 17, 2014). The task force was established by Executive Order 13653.
- ⁷⁸ The FrameWorks Institute is an independent nonprofit organization with a mission of advancing the nonprofit sector's communications capacity by identifying, translating and modeling relevant scholarly research for framing the public discourse about social problems. As of August 11, 2015, these fact sheets had not yet been finalized. CDC is providing funding for this effort through a cooperative agreement with the American Public Health Association.
- ⁷⁹ See HHS, *HHS Climate Adaptation Plan 2014* (Washington, D.C., July 3, 2014), p.7. A senior HHS official from HHS component responsible for developing this strategy also told us that the strategy is intended to have multiple goals, including communicating to the general public on the risks that climate change poses to public health, as well as multiple audiences such as health care providers, public health officials, and other decision makers.
- ⁸⁰ See HHS, *Strategic Sustainability Performance Plan* (Washington, D.C.; July 17, 2014), p.50.
- ⁸¹ Centers for Disease Control and Prevention, *Climate Change, Extreme Heat, and Health: A Tool Kit*, http://ephtracking.cdc.gov/docs/CDC_ClimateChange_Final.pdf (accessed May 1, 2015).
- ⁸² CDC has issued a document that describes the risks posed by extreme heat events, and includes some information that could be used in developing communications to the public about heat. However, this document is not focused on how to communicate on a broader level about the risks climate change poses to public health. Centers for Disease Control and Prevention, *Climate Change and Extreme Heat Events*, <http://www.cdc.gov/climateandhealth/pubs/ClimateChangeandExtremeHeatEvents.pdf> (accessed July 16, 2015).
- ⁸³ The program has also identified priority actions to meet these core functions, such as communicating the health-related aspects of climate change, including risks and ways to reduce those risks, to the public, decision makers, and healthcare providers.
- ⁸⁴ According to HHS officials, geographic information systems can be used to overlay public health disease data with climatic datasets, such as temperature and precipitation information, to determine if associations exist.
- ⁸⁵ We previously reported that future federal adaptation efforts could better focus on providing local climate change assistance, including with regard to translating climate data for decision makers. See GAO, *Climate Change: Future Federal Adaptation Efforts Could Better Support Local Infrastructure Decision Makers*, GAO-13-242 (Washington, D.C.: Apr. 12, 2013).

- ⁹⁷ See C. Emrich, D. Morath, G. Bowser, R. Reeves, *Climate-Sensitive Hazards in Florida: Identifying and Prioritizing Threats to Build Resilience against Climate Effects*. <http://www.floridahealth.gov/environmental-health/climate-and-health/documents/climate-sensitive-hazards-in-florida-final-report.pdf> (accessed September 10, 2014).
- ⁹⁸ See San Francisco Department of Public Health. San Francisco Climate & Health Profile. http://www.sfclimatehealth.org/wp-content/uploads/2015/01/SFDPH_ClimateHealth_Profile_FinalDraft.pdf (accessed April 15, 2015). According to officials from San Francisco, information sources used to develop the indicators

included data from the U.S. Census Bureau and the American Community Survey, and many of the indicators are based on those established by the University of South Carolina's Social Vulnerability Index, which measures the social vulnerability of U.S. counties to environmental hazards. Data used in the development of the indicators were also made available for researchers, decision makers, and the public, in an effort to promote transparency and encourage the development of tools to address climate change.

⁹⁹ According to these officials, resources used to conduct this work include federal and state funding sources, as well as partnerships with academic institutions or nongovernmental organizations.

¹⁰⁰ Specifically, in July 2004, over 60 passengers aboard cruise ships near Alaska became ill after eating raw oysters, resulting in one of the largest known outbreaks of *vibrio parahaemolyticus* ever reported in the United States. During this outbreak, Department of Health officials worked to study the disease and process oyster samples, and later published the results of their study. See J. McLaughlin, et al., "Outbreak of *Vibrio parahaemolyticus* Gastroenteritis Associated with Alaskan Oysters," *The New England Journal of Medicine* 353, no. 14 (2005).

¹⁰¹ The Local Environmental Observers network was developed by the Alaska Native Tribal Health Consortium's Center for Climate and Health with funding from EPA and the Western Alaska Landscape Conservation Cooperative—a partnership of federal agencies and other stakeholders addressing climate change impacts on the nation's landscapes.

¹⁰² President's State, Local, and Tribal Leaders Task Force on Climate Preparedness and Resilience, *Recommendations to the President* (Washington, D.C.: Nov. 17, 2014). The task force terminated 6 months after it provided its recommendations. In July 2015, the administration issued a progress report, providing examples of federal actions taken to address these recommendations. The White House, *Progress Report: Highlighting Federal Actions Addressing the Recommendations of the State, Local, and Tribal Leaders Task Force on Climate Preparedness and Resilience* (Washington, D.C.: July 2015).

Chapter 537

**TESTIMONY OF ANTHONY S. FAUCI,
DIRECTOR, NATIONAL INSTITUTE OF ALLERGY AND
INFECTIOUS DISEASES, NATIONAL INSTITUTES OF
HEALTH. HEARING ON “EXAMINING THE U.S.
PUBLIC HEALTH RESPONSE TO THE ZIKA VIRUS”***

Mr. Chairman, Ranking Member DeGette, and Members of the Subcommittee:

Thank you for the opportunity to discuss the National Institutes of Health (NIH) research response to Zika virus, an emerging public health threat of international concern. I direct the National Institute of Allergy and Infectious Diseases (NIAID), the lead NIH institute for conducting and supporting research on emerging and re-emerging infectious diseases, including those caused by flaviviruses such as Zika virus.

The Administration is taking appropriate action to protect the American people and, as you know, it announced a request to Congress for approximately \$1.9 billion in emergency funding to enhance ongoing efforts to prepare for and respond to outbreaks of the Zika virus, both domestically and internationally. This includes funding for work on the development of vaccines and diagnostics and to improve scientific understanding of the disease.

The overarching mission of NIAID is to conduct and support research to better understand, treat, and prevent infectious and immunologic diseases. This is accomplished through a spectrum of research, from basic studies of the mechanisms of disease to applied research focused on developing interventions such as diagnostics, therapeutics, and vaccines. As part of this mission, NIAID has a dual mandate encompassing both research on ongoing public health issues and the capability to respond rapidly to newly emerging and re-emerging infections such as Zika virus.

These emerging and re-emerging disease threats, whether man-made or naturally occurring, are perpetual challenges, in part due to the capacity of microbial pathogens to evolve rapidly and adapt to new ecological niches. To address the challenges posed by

* This is an edited, reformatted and augmented version of testimony presented March 2, 2016 before the House Committee on Energy and Commerce, Subcommittee on Oversight and Investigations.

emerging infectious diseases, NIAID employs both targeted, disease-specific research as well as broad-spectrum approaches. NIAID maximizes its efforts by prioritizing the development of drugs effective against multiple bacteria or viruses, and “platform” technologies to facilitate rapid development of vaccines and diagnostics applicable to multiple infections.

NIAID is well-positioned to rapidly respond to infectious disease threats as they emerge by leveraging fundamental, basic research efforts; domestic and international research infrastructure that can be quickly mobilized; and productive partnerships with industry. NIAID provides preclinical research resources to scientists in academia and private industry worldwide to advance translational research against emerging and re-emerging infectious diseases. These resources are designed to bridge gaps in the product development pipeline and lower the scientific, technical, and financial risks incurred by industry in order to incentivize them to partner with us in the advanced development of effective countermeasures. NIAID also supports our Vaccine and Treatment Evaluation Units (VTEUs), a research network that conducts clinical trials to quickly investigate promising therapeutic and vaccine candidates when public health needs arise. NIAID collaborations with other federal agencies, including those undertaken within the Department of Health and Human Services (HHS) Public Health Emergency Medical Countermeasures Enterprise (PHEMCE), help advance progress against newly emerging public health threats. In addition, partnerships with academia, the biotechnology and pharmaceutical industries, and international researchers and organizations such as the World Health Organization (WHO) and WHO’s regional office, the Pan American Health Organization (PAHO), are integral to these efforts.

OVERVIEW OF ZIKA VIRUS

Zika virus is a flavivirus. These viruses typically are transmitted by mosquitoes and often have the ability to spread quickly to new geographic locations because of the widespread prevalence of these vectors. Other well-known flaviviruses include dengue virus and yellow fever virus; like Zika virus they are transmitted by *Aedes* mosquitoes. Zika virus was discovered in monkeys in Uganda in 1947 and is now endemic to Africa and Southeast Asia. During the past decade it has emerged in other areas of the world, including Oceania, the Caribbean, and Central and South America, where countries, notably Brazil, are currently experiencing unprecedented Zika transmission.

Infections caused by Zika virus are usually asymptomatic. About 20 percent of infected individuals experience clinical symptoms such as fever, rash, joint pain, and conjunctivitis (red eyes). Symptoms of Zika virus infection in humans are typically mild and brief, with very low hospitalization and fatality rates. The recent outbreak of Zika virus disease in Brazil has coincided with a reported increase in the number of infants born with microcephaly, a birth defect characterized by an abnormally small head resulting from an underdeveloped and/or damaged brain. In addition, increases in suspected cases of Guillain-Barré syndrome (GBS), a rare, acute, immune-mediated peripheral nerve disease that leads to weakness, sometimes paralysis, and infrequently, respiratory failure and death, have been noted in Brazil and other countries in the Americas.

Further research is needed to better understand the effect of Zika virus infection on the body, particularly during pregnancy; to investigate the potential relationship between Zika infection and congenital abnormalities including microcephaly, as well as to explore the potential relationship between Zika infection and GBS; and to develop better diagnostics, vaccines and treatments, and new methods of vector control. Currently, no vaccines or specific therapeutics are available to prevent or treat Zika virus disease. Improved diagnostic tests also are needed because Zika virus infection causes non-specific symptoms or no symptoms at all and can be difficult to distinguish by antibody screening tests from other mosquito-borne infections such as dengue, malaria, and chikungunya. Moreover, current antibody screening tests can be falsely positive or inconclusive if the individual was previously infected with related viruses such as dengue, which is prevalent in South America and the Caribbean. Therefore, a positive result with the antibody screening test requires an additional test to confirm the diagnosis.

NIH RESEARCH ON ZIKA VIRUS

NIAID has a longstanding commitment to flavivirus research, including extensive efforts to combat diseases such as dengue, West Nile virus, and yellow fever. This research has informed our understanding of the viral genetics, vector biology, and pathogenesis of flaviviruses and provides a strong foundation for our efforts to learn more about Zika virus. NIAID has responded to the newly emerging Zika virus disease outbreak by expanding our portfolio of basic research on Zika virus and other flaviviruses. NIAID also is accelerating efforts to develop improved diagnostics and candidate therapies for Zika virus as well as prioritizing the development of Zika virus vaccines. In addition, screening tests and pathogen reduction technologies are critically important to assure safety of the U.S. blood supply.

The emergency funding for NIH would support development of vaccines to prevent Zika virus infection, from the discovery phase through preclinical and eventually clinical testing. In addition, the funds would support basic research to understand the natural history, viral biology and pathogenesis, including potential links to microcephaly; establishment of animal models to test candidate countermeasures; development of rapid, sensitive, and specific diagnostic tests; and discovery and preclinical development of new therapeutics to treat disease caused by Zika virus. This research is necessary to better understand this emerging infection and uncover the best ways to diagnose, treat, and prevent Zika virus disease.

In January 2016, NIAID issued a notice to researchers highlighting NIH's interest in supporting research and product development to combat Zika virus. Areas of high priority include basic research to understand viral replication, pathogenesis, and transmission, as well as the biology of the mosquito vectors; potential interactions with co-infections such as dengue and yellow fever viruses; animal models of Zika virus infection; and novel vector control methods. In addition, NIH is soliciting Zika virus research to develop sensitive, specific, and rapid clinical diagnostic tests; drugs against Zika virus as well as broad spectrum therapeutics against multiple flaviviruses; and effective vaccines and vaccination strategies.

NIAID also is partnering with other NIH institutes, the *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NICHD), the National Institute of Neurological Disorders and Stroke (NINDS), and the National Institute of Dental and

Craniofacial Research, to accelerate Zika virus research as it relates to the mother-infant pair. The Institutes issued a notice that indicates NIH's interest in supporting research to understand transmission, optimal screening and management in pregnancy, and the mechanisms by which Zika virus affects the developing nervous system, including potential links to microcephaly and other congenital abnormalities.

DEVELOPING TOOLS TO COMBAT ZIKA VIRUS

In response to public health concerns about Zika virus, NIAID has accelerated ongoing flavivirus research efforts to speed the development of tools that could help control current and future outbreaks of Zika virus.

Vector Control

For many years, NIAID has supported extensive research to understand the biology of mosquitoes to help develop tools to limit the spread of deadly mosquito-borne diseases such as dengue and malaria. This research aids in vector control strategies to reduce mosquito bites or limit mosquito populations. In the Americas, Zika virus is transmitted primarily by *Aedes aegypti* mosquitoes, and vector control or other methods to prevent exposure to these mosquitoes are currently the only ways to prevent Zika infection. NIAID plans to support vector competence studies to test various mosquito species for their ability to carry and transmit Zika virus and for insecticide resistance. Understanding the specific mosquito species involved in Zika outbreaks and which insecticides may be effective against them will aid current vector control efforts and may inform novel mosquito control strategies in the future.

Diagnostics

Accurate diagnostic tests for Zika virus infection are needed to distinguish it from other flavivirus infections and to identify women who have been infected with Zika virus during pregnancy and may be at risk for developing fetal complications. Blood, organ, and tissue donor screening tests are also needed to assure the safety of transfusion and transplantation in areas of active mosquito-borne virus transmission. Currently, Zika virus itself can often be detected during the acute phase of infection and up to seven days after the onset of symptoms using diagnostic tests for viral RNA (RT-PCR test). While prior infection can be detected by testing for the presence of antibodies against Zika virus, assays for Zika antibodies may also detect or cross-react with antibodies against other flaviviruses, particularly dengue virus. For this reason, a positive antibody test does not definitively confirm prior Zika virus infection in the setting of possible co-infection or prior infection with dengue and other related viruses, and separate confirmatory testing is required. This is a particular concern in South America where there is a high level of exposure to other flaviviruses, particularly dengue virus.

To facilitate the development of improved Zika virus diagnostic tests, NIAID grantees are working to generate antibodies that can distinguish between Zika virus and dengue virus. They also are working to identify biosignatures unique to Zika infection that could form the basis of additional rapid, specific, and sensitive diagnostic tests. In addition, NIAID is pursuing the development of a mouse model of Zika virus infection that could be used to test new diagnostic and therapeutic tools.

Vaccines

A safe and effective Zika vaccine would be a very valuable tool to help stop the spread of infection and prevent future outbreaks. NIAID is investigating multiple Zika virus vaccine candidates, including vaccines based on technologies that have shown promise in targeting other flaviviruses. The NIAID Vaccine Research Center (VRC) is pursuing a DNA-based vaccine for Zika virus that is similar to a West Nile virus vaccine previously developed by NIAID. The West Nile vaccine candidate was shown in Phase 1 testing to be safe and generated a strong immune response in humans, offering a model for Zika vaccine development. NIAID scientists also are designing a live, attenuated vaccine, using an approach similar to that used for making a vaccine against the closely related dengue virus. The dengue vaccine candidate showed an excellent safety profile and generated strong immune responses in early-phase clinical trials. In January, a large Phase 3 trial assessing the dengue vaccine candidate was launched in Brazil in collaboration with the Butantan Institute. In addition, NIAID grantees are in the early stages of developing a Zika virus vaccine based on a recombinant vesicular stomatitis virus – the same animal virus used successfully to create an investigational Ebola vaccine. Plans are underway to evaluate this potential vaccine construct in tissue culture and animal models.

While these approaches are promising, it is important to realize that the development of investigational vaccines and the clinical testing to establish whether they are safe and effective takes time. Although a safe and effective, fully licensed Zika vaccine will likely not be available for a few years, we plan to begin early-stage clinical testing of one or more NIAID-supported vaccine candidates in 2016.

Therapeutics

NIAID has an active program to screen for antiviral drugs active against viruses in the flavivirus family, including dengue, West Nile, yellow fever, and Japanese encephalitis viruses, as well as the closely related hepatitis C virus. NIAID has enhanced these efforts with the recent development of an assay to test compounds for antiviral activity against Zika virus. NIAID will make this test available to the research community and will soon test 10 antiviral compounds with activity against other flaviviruses to determine if they are effective against Zika virus. Promising drug candidates identified by the assay could be further tested in a small animal model of Zika virus infection developed with NIAID support. The ultimate goal of NIAID-supported flavivirus therapeutic research is to develop a broad-spectrum antiviral drug that could be used against a variety of flaviviruses, including Zika.

Emergency Request for Vaccine Research and Diagnostic Development and Procurement

As I noted in the introduction to my testimony, the Administration has announced an emergency funding request of approximately \$1.9 billion to combat the Zika virus both domestically and internationally. Included in the request are resources for Zika-related vaccine research, rapid advanced development, and commercialization of new vaccines and diagnostic tests for Zika virus. The funding will allow NIH to build upon existing resources and work to develop a vaccine for Zika virus and the chikungunya virus, which is spread by the same type of mosquito. Funding will accelerate this work and improve scientific understanding of the disease to inform the development of additional tools to combat it. The request also includes resources for FDA to support Zika virus medical product development, including the next-generation diagnostic devices. We look forward to working with the Congress to implement this request.

COLLABORATIONS

Investigation of emerging and re-emerging infectious diseases requires expertise from a variety of fields. In the case of Zika virus, studies of virology, immunology, natural history, neurology, and neonatology will be required to fully understand the pathogenesis of this infection. As mentioned previously, NIAID is partnering with other NIH institutes including NICHD and NINDS to better understand the potential association between Zika virus infection and neonatal defects, particularly microcephaly.

NIAID also is employing partnerships with research institutions in South America to advance research on Zika virus infection; additional collaborations with academic, industry, and government partners are under active exploration. NIAID held a joint meeting in December 2015 with Brazilian research institute Fiocruz in which Zika was a key area of concentration. In addition, NIAID is collaborating with other HHS agencies in responding to the Zika epidemic. For example, NIAID, CDC, BARDA, ASPR, and FDA are jointly convening a Zika virus workshop on March 28-29, 2016, where the latest information on Zika virus will be discussed by experts from Federal Agencies, academia, and pharmaceutical and biotechnology companies. Topics to be addressed at the workshop include virology, epidemiology, possible links to microcephaly, and efforts to develop diagnostics, therapeutics, and vaccines.

CONCLUSION

NIH is committed to continued collaboration with HHS agencies and other partners across the U.S. government in advancing research to address Zika virus infection, and we look forward to working with the Congress to implement the President's emergency funding request. As part of its mission to respond rapidly to emerging and re-emerging infectious diseases throughout the world, NIAID is expanding our efforts to elucidate the biology of

Zika virus and employ this knowledge to develop needed tools to diagnose, treat, and prevent disease caused by this virus. In particular, NIAID will pursue the development of safe, effective vaccines to prevent disease caused by Zika and chikungunya viruses.

Chapter 538

**TESTIMONY OF JOSEPH M. CONLON, TECHNICAL
ADVISOR, AMERICAN MOSQUITO CONTROL
ASSOCIATION. HEARING ON “EXAMINING THE U.S.
PUBLIC HEALTH RESPONSE TO THE ZIKA VIRUS”***

Good morning, Mr. Chairman and Members of the Subcommittee. My name is Joseph Conlon and I am a retired U.S. Navy medical entomologist serving as Technical Advisor for the American Mosquito Control Association (AMCA), a nonprofit organization of 1600 members dedicated to enhancing health and quality of life through the suppression of mosquitoes and other vectors of public health importance. I welcome this opportunity to provide a mosquito control perspective to the deliberations of this committee concerning Zika Virus and will limit my testimony to mosquito management methodologies that contribute to its control.

The introduction and spread of Zika Virus in Central and South America and the Caribbean in 2014 reawakened in the United States an appreciation of mosquitoes as vectors of diseases. I use the term “reawakened” advisedly, for mosquito-borne diseases such as malaria and yellow fever were once quite prevalent in the United States and, indeed, played a major part in shaping our nation’s destiny. These diseases no longer claim victims in the United States as a matter of course largely due to the exemplary efforts of organized mosquito control agencies, in conjunction with an enlightened and effective public health infrastructure. But other mosquito-borne diseases are on the horizon and public health agencies need to be prepared to meet the challenges they present.

Progress continues in defining the transmission dynamics of Zika Virus so as to allow for its prevention and control. However, considering that it is a comparatively recent epidemiological phenomenon, there remains much to learn in order to establish and verify baseline data. The virus is thought to be primarily transmitted from human to human by the bite of infected *Aedes aegypti* and (possibly) *Aedes albopictus* species of mosquitoes. Of these, *Aedes aegypti* has been primarily responsible for transmitting the disease due to its preference to bite humans both day and night and its predilection for biting the lower

* This is an edited, reformatted and augmented version of testimony presented March 2, 2016 before the House Committee on Energy and Commerce, Subcommittee on Oversight and Investigations.

extremities. Moreover, females frequently take multiple partial bloodmeals, often from different individual humans, not only increasing the likelihood of feeding on an infectious human but also leading to single infectious females potentially feeding on and infecting multiple humans within a relatively short time period.

Aedes aegypti and *Aedes albopictus* are notoriously difficult to prevent or kill. They live inside our houses under furniture, beds and in closets; their eggs can withstand months of drying, and their young can develop in water containers as small as a bottle cap. Virtually any collection of stagnant water in containers, treeholes, leaf axils, etc. can serve as egg-laying habitat for these species. Thus, draining wet areas doesn't prevent their development around our homes and yards; predators do not consume enough to provide effective control; and repellents, while protecting individuals, just redirect the adult mosquitoes to bite somebody else.

Aedes aegypti has been found in isolated areas of California, and from Arizona, New Mexico, Texas, Louisiana, Mississippi, Alabama, Florida, Georgia and South Carolina. *Aedes albopictus* is a more cold-hardy species and its range includes those states but extends northward to Illinois and New York. Its range is thought to be defined by an average winter temperature of 50 degrees Fahrenheit.

MOSQUITO CONTROL AS CURRENTLY PRACTICED IN THE UNITED STATES

The first mosquito control districts were established in NJ in 1912. California and Florida followed suit in 1915 and 1925, respectively. In the ensuing years, mosquito control districts and state agencies were established nationwide so that there are now more than 700 recognized districts within the United States along with over 1000 control entities within municipal service programs.

The integrated mosquito management methods currently employed by these organized control agencies and endorsed by the CDC and EPA are comprehensive and specifically tailored to safely counter each stage of the mosquito life cycle. Larval control through water management and source reduction, where compatible with other land management uses, is a prudent pest management alternative - as is use of the environmentally friendly EPA-approved larvicides currently available. When source elimination or larval control measures are clearly inadequate, or in the case of imminent disease, the EPA and CDC have emphasized in a published joint statement the need for considered application of adulticides by certified applicators trained in the special handling characteristics of these products.

In 2009 the AMCA published its "Best Management Practices for Integrated Mosquito Management" and promulgated it to its membership as a set of guidelines for safe, effective and efficient vector control programs. The AMCA is currently in the process of developing guidelines specifically geared toward control of *Aedes aegypti* and *Aedes albopictus*. This will emphasize urban mosquito control and the paradigm shift in control practices from floodwater/salt marsh mosquitoes (predictable habitats) to container-inhabiting mosquitoes (unpredictable and ubiquitous in the peridomestic environment). In addition, the unique manpower, resources, and funding needed for proactive urban control will be covered. AMCA hopes to have a finalized version available as early as possible in 2016/2017 timeframe.

States thought to be particularly susceptible to Zika introduction, such as Florida, California, and Texas, have excellent integrated mosquito control programs in many areas, but emergency funds to respond to a Zika outbreak are needed if timely interventions to contain outbreaks in these districts and elsewhere are to be realized. Critically, many potential ports of entry throughout the U.S. have limited or no mosquito control available and there is a pressing need for funding to establish sustainable mosquito control programs in these areas.

Components of successful mosquito-borne disease control programs as currently practiced in the United States include, but are not limited to, the following:

Prevention

Surveillance - A sustained, consistent surveillance program targets the particular vector species, mapping their larval habitats by season, and documents the need for control through larval and adult trapping regimens. It thus also monitors the effectiveness of the control program. Appropriate and timely response to surveillance data is the key to preventing human disease associated with Zika. Control activity should then be intensified in response to evidence of virus in imported cases, as deemed necessary by the local statutory authority.

Public Information and Outreach – Studies have shown that information programs, while crucial to the overall prevention/control strategy, only exert a moderate effect on modifying population behaviors related to personal protective measures. Effective programs include development of a community task force, interventions to improve access to window screening materials or repellents, and social marketing to reinforce preventive behaviors. These are critical components of any mosquito control program, but cannot, in and of themselves, replace established prevention/control methodologies.

Source Reduction - Removing breeding habitat is the most effective long-term mosquito preventative/control and includes activities as simple as the proper disposal of used tires, paint cans and trash, in addition to the cleaning of rain gutters and bird baths, by individual property owners.

Control

Reducing the contact between the vector mosquito and humans - This is accomplished through removing, modifying or treating larval habitats; modification or removal of adult mosquito resting areas, adulticide treatments when indicated, and use of repellents. All of these interventions can be problematic regarding control of *Aedes aegypti*.

Best Management Practices (BMP) - Most larger mosquito control districts in states having potential ports of entry, such as California, Texas and Florida, usually employ a phased response based upon mosquito trapping data. Such programs consist of public education emphasizing personal protection and residential source reduction; municipal larval control to prevent repopulation of the area with competent vectors; adult mosquito control to decrease the density of infected, adult mosquitoes in the area; and continued surveillance to monitor virus activity and efficacy of control measures.

How Mosquito Control Can Be Improved

- Mosquito surveillance tools for adult *Aedes aegypti* are ineffective for small populations and need to be improved and made more widely available to marginally funded programs.
- Training in the use and interpretation of survey results should be made available to both program managers and public health officials as continuing education adjuncts.
- Additional training resources and comprehensive participation in workshops and professional mosquito control conferences are key components of program upgrades.
- Faster and more efficient communications between public health laboratories and vector control programs need to be explored and implemented. The speed with which the public health sector can respond to either imported or locally-acquired cases will ultimately depend on the turnaround time between testing of suspect cases, laboratory confirmation and promulgation of surveillance results. In addition, variable interpretations of the Health Insurance Portability and Accountability Act (HIPAA) may delay release of results, further restricting timely interventions by vector control agencies. Mechanisms need to be developed that require health departments at all levels to disclose to local vector control agencies the location of suspect cases of Zika while not violating HIPAA provisions. This will ensure more timely and targeted initiation of intervention measures that will prevent or rapidly contain outbreaks.
- Materials and training regarding pesticide resistance testing should be implemented nationwide.
- Funds should be made available to underwrite new data call-ins that might influence a pesticide registrant's decision to keep products on the market
- New chemical, genetic, and biological control methodologies and means of dispersal should be developed and field validated.
- Conventional pesticides are losing ground to resistance. New tools are in development (spatial repellents, ATSB, lethal ovitraps, intracellular biological control (*Wolbachia*), RNAi, GMO mosquitoes, and new pesticide chemical classes require more field validation prior to widespread use.
- Rapid diagnostic tests for Zika and other arboviral agents need development and deployment to mosquito control entities to provide timely notification of infected mosquitoes prior to human cases.

THE ROLE OF FEDERAL GOVERNMENT

The federal government has a crucial role to play in how vector control is accomplished. Several agencies either conduct (e.g., USDA and to a lesser degree CDC) research on applied vector control topics, or fund (NIH) projects (e.g., *Wolbachia*) into novel technologies, FEMA supports large-scale vector control in declared disasters (under Stafford Act stipulations).

In addition, the Centers for Disease Control and Prevention (CDC) Division of Vector-borne Disease provides national expertise in mosquito-borne disease prevention and control

in concert with members of the AMCA. They have also served as an effective conduit via the Expanded Laboratory Capacity (ELC) program for funding that can increase arboviral testing capacities at both state and local levels. To this end, we encourage Congress to authorize supplemental funding for 2016 and increased funding in FY 2017 to support vector-borne disease surveillance. Funding should be allocated through the Centers for Disease Control and Prevention's (CDC's) Division of Vector-Borne Diseases for dispersal to localities most vulnerable to disease introduction while lacking the capabilities.

The Mosquito Abatement for Public Health Act (MASH), Public Law 108-75, was passed during the first session of the 108th Congress but has not received appropriations for its implementation. This Act is a mechanism by which local governments could receive matching federal funds up to \$100,000 for the establishment and/or enhancement of a mosquito abatement program through the CDC. The MASH Act authorized \$100,000,000 in funds for FY 2003, but, as of this hearing, Congress has still not appropriated any funds to cover its provisions. In addition, it requires NIEHS to conduct or support research into methods to control the population of insects and vermin that transmit dangerous diseases to humans. The AMCA fully supports the MASH Act and requests action to appropriate the funds for its full implementation to bolster long-term vector surveillance and control.

The critical challenge for the nation's public health system will be modifying the behavior of the US population to eliminate oviposition sites for these species. Vector control agencies do not possess the resources to provide the sustained service for each resident in their jurisdiction that is required to successfully control invasive *Aedes*. To accomplish that end via source reduction will entail a national effort, along the lines of the "buckle up" seat belt, Smoky the Bear, and "don't be a litterbug" campaigns of the 1960s. A sustained national program will require continued funding into the foreseeable future if the benefits from reduced introduction and spread of exotic mosquito-borne diseases are to be realized.

We further see a federal government role in maintaining our present, proven chemical tools at risk of losing their registration. In 1996 Congress unanimously approved the Food Quality Protection Act (FQPA) (PL 104-170) to modernize the regulation of pesticides and expand data requirements to demonstrate their safety to people and the environment. A key element was authorization to use federal funds when the cost of new data for public health pesticides was more than their producers could afford, putting registration at risk. Unfortunately, these essential funds have never been appropriated, and we are now losing critical public health tools because the cost to prove their safety is higher than return on investment.

CONCLUSION

Vector-borne diseases, whether ancient like malaria or relatively new like Zika, are an unfortunate reality, and Zika won't be the last to challenge our vector-borne disease control capabilities. There are many factors that contribute to the emergence of novel vector-borne diseases, including poverty, climate change, and global trade. They will require long-term solutions.

Mosquito control capabilities in the United States are the finest in the world, but in many cases, fall short of providing the level of protection needed to prevent outbreaks of mosquito-

borne disease in all potential ports of entry. Increased tourism and trade make continual introductions of exotic diseases inevitable and resources for sustainable prevention and control programs must be made available so that future imported cases of exotic diseases beyond Zika can be contained and eliminated before their establishment and spread. Our citizenry deserves no less.

SUMMARY

- Capacities to address mosquito-borne diseases in the U.S. are better than in the past, but require significant improvement to successfully meet the mosquito-borne disease threats such as Zika Virus surely to come our way in the future.
- Increased capacity must include capabilities to address survey control strategies applicable to the widest possible variety of vector-borne disease transmission cycles.
- The unique bionomics of *Aedes aegypti* require better surveillance and prevention/control tools and strategies over the long-term.
- The Federal role should consist of exploring and implementing funding mechanisms devoted to increasing sustainable integrated vector surveillance and control capabilities in areas with organized mosquito control and to develop startup programs in areas of potential risk.
- The MASH act proposes just that sort of thing – providing support for developing new vector control where lacking, and enhancing capacities where they exist but are inadequate.
- Fully fund the Food Quality Protection Act provisions to use federal funds when the cost of new data for existing public health pesticides is more than their producers can afford, putting their registration at risk.
- Increase the CDC/DVBD annual budget to levels that allow funds to be allocated directly for testing of mosquito pools conducted at the local mosquito control program level or intrastate testing collaborative below the state level.

Chapter 539

**STATEMENT OF DR. LUCIANA BORIO, ACTING CHIEF
SCIENTIST, U.S. FOOD AND DRUG ADMINISTRATION.
HEARING ON “EXAMINING THE U.S. PUBLIC
HEALTH RESPONSE TO THE ZIKA VIRUS”***

INTRODUCTION

Good morning Chairman Murphy, Ranking Member DeGette, and members of the Subcommittee. I am Dr. Luciana Borio, Acting Chief Scientist at the Food and Drug Administration (FDA or the Agency). Thank you for the opportunity to appear today to discuss FDA’s actions in response to the Zika virus outbreak.

As you know, Zika virus was first identified in 1947 in Uganda. Since then, sporadic cases and a few outbreaks have been recognized in a number of locations, including parts of Africa, Asia, and the Pacific. However, the situation has changed dramatically since May 2015, when the first local transmission of Zika virus in the Americas was confirmed in Brazil. By December 2015, Brazil had reported more than 56,000 suspected cases of Zika virus and has since stopped counting cases due to the magnitude of the outbreak, which Brazilian national authorities estimate to encompass from approximately 500,000 to 1.5 million cases.

Zika virus is now spreading throughout Latin America and the Caribbean, as well as in parts of the Pacific and Africa. As of February 25, 2016, 34 countries and territories, including the Commonwealth of Puerto Rico, the U.S. Virgin Islands, and American Samoa, have active, local transmission of Zika virus.

Potential links between Zika virus infection and neurological complications (e.g., Guillain-Barré Syndrome), as well as microcephaly and other poor pregnancy outcomes in babies of mothers who were infected with Zika virus during their pregnancy have dramatically increased concerns about the risks associated with Zika virus. On February 1, 2016, the World Health Organization (WHO) declared the recent clusters of microcephaly and other neurological disorders a public health emergency of international concern.

* This is an edited, reformatted and augmented version of a statement presented March 2, 2016 before the House Committee on Energy and Commerce, Subcommittee on Oversight and Investigations.

No locally transmitted mosquito-borne Zika virus disease cases have been reported in the continental United States to date. There have, however, been travel-associated cases, as well as local cases of sexual transmission to women whose only known risk factor was sexual contact with an infected male partner who traveled to an area with active transmission. These imported cases have the potential to result in local spread of Zika virus in areas of the United States where *Aedes* mosquitoes that transmit Zika virus are found. CDC and state, local, and territorial health departments are monitoring for any such events.

FDA RESPONSE TO THE ZIKA VIRUS OUTBREAK

FDA is working in collaboration with other components of the Department of Health and Human Services (HHS), including the Office of the Assistant Secretary for Preparedness and Response (ASPR) and its Biomedical Advanced Research and Development Authority (BARDA), the National Institutes of Health (NIH), and the Centers for Disease Control and Prevention (CDC), as well as with partners across the U.S. Government and with international partners to respond to the Zika virus outbreak. FDA's primary areas of activity include: (1) protecting the safety of the nation's blood supply and tissues for transplantation; (2) facilitating the development of donor screening and medical diagnostic tests that may be useful for identifying the presence of, or prior exposure to, Zika virus; (3) supporting the development of investigational vaccines and therapies; (4) reviewing proposals for the use of innovative strategies to help suppress the population of virus-carrying mosquitoes; and (5) protecting the public from fraudulent products that claim to prevent, diagnose, treat, or cure Zika virus disease.

Blood Supply and Tissue Safety

In the absence of an available donor screening assay, the risk of transmission of Zika virus by blood transfusion is considered likely, based on the most current scientific evidence of how Zika virus and other flaviviruses (including West Nile and dengue) are spread, as well as recent reports of transfusion-associated infection outside of the United States. Realizing this risk, and to better protect the U.S. blood supply, FDA issued new Zika-related blood donor guidance. In areas with active Zika virus transmission, FDA recommends that whole blood and blood components for transfusion be obtained from areas of the United States without active transmission. Blood establishments may continue collecting and preparing platelets and plasma if an FDA-approved, pathogen-reduction device is used. FDA also recommends deferral from donating blood for four weeks for individuals in areas without active Zika transmission if they a) have been to areas with active Zika virus transmission; b) have recovered from an illness with symptoms suggestive of Zika virus infection that developed within two weeks of exposure in an affected area; or c) have had sexual contact with a man who has traveled to, or resided in, an area with active Zika virus transmission during the prior three months. The guidance also recommends that blood establishments update donor education materials with information about Zika virus signs and symptoms, ask potentially affected donors to refrain from giving blood, and update the donor history

questionnaire to elicit information on recent exposure to an affected area. FDA is working with public health authorities in territories with confirmed Zika virus to take rapid and appropriate steps to ensure that safe blood is available.

In addition, to advance blood safety against Zika virus, FDA is facilitating the development of screening tests for identifying the presence of the virus in donated blood and pathogen-reduction technologies to kill viruses in blood components through establishment of reference materials, clarification of regulatory pathways, and interactive review of sponsor-submitted data.

Furthermore, FDA is developing guidance that will address appropriate donor deferral measures for human cells, tissues, and cellular and tissue-based products. This guidance is particularly important given evidence of sexual transmission of Zika virus.

Diagnostic Tests

Unfortunately, there are no commercially available diagnostic tests cleared by FDA for the detection of Zika virus. Two types of diagnostic tests are needed for Zika virus: (1) a test to diagnose acute infection; and (2) a test to assess whether individuals, especially pregnant women, who were potentially exposed to Zika virus were actually infected. In keeping with FDA's practice for responding to emerging infectious disease outbreaks, FDA has been reaching out to potential diagnostic manufacturers to encourage them to develop needed diagnostic tests for Zika virus. In addition, FDA is working interactively with diagnostic manufacturers interested in developing diagnostic tests for Zika virus to help accelerate development programs, including clarifying data requirements for the authorization of the use of Zika diagnostic tests under FDA's Emergency Use Authorization authority (EUA). FDA has authorized the use of a Zika virus diagnostic test developed by CDC under EUA for the qualitative detection of Zika virus-specific immunoglobulin M (IgM) antibodies by qualified laboratories. This diagnostic test can help expand domestic readiness for Zika virus by enabling the identification of patients recently infected with Zika virus in support of response efforts. The authorized test has already been made available to 19 states and territories. FDA is ready to authorize the use of additional

Zika virus diagnostic tests under our EUA authority as soon as we receive data regarding the accuracy and precision of the test from a diagnostic manufacturer to enable such authorization.

Vaccines and Therapies

There are no vaccines or treatments in advanced development for Zika virus at this time. Development programs for investigational vaccines and therapies are in the very early stages and FDA is actively engaged with NIH and BARDA to help accelerate development programs. FDA stands ready to work with medical product developers to provide technical support and clarify regulatory and data requirements necessary to move products forward in development as quickly as possible.

Vector Control

In the United States, mosquito control is typically achieved by a multi-faceted approach that includes a range of tools, including surveillance of mosquito activity, reduction in breeding sites, and the use of chemical and biological control methods. There has been public discussion of a new method to potentially help control mosquito populations through the use of a genetically engineered (GE) line of the mosquito *Aedes aegypti* (OX513A) developed by Oxitec, Ltd. The release of male Oxitec GE mosquitoes is intended to cause suppression of the mosquito population in a release area over time because the offspring resulting from the mating of male GE mosquitoes with wild type females do not develop to adulthood. The Brazilian National Biosafety Commission found the Oxitec GE mosquito safe for use in Brazil in 2014 after extensive field testing, and open field trials of these GE mosquitoes have also been conducted in the Cayman Islands, Panama, and Malaysia. Although multiple pilot studies have been authorized in Brazil, the country's national regulatory authority, the Agência Nacional de Vigilância Sanitária (ANVISA), is currently reviewing Oxitec's request to approve its product for commercial sale.

FDA is reviewing information in an Investigational New Animal Drug (INAD) file from Oxitec regarding the potential use of the company's GE mosquito with the intent of suppressing the population of *Aedes aegypti* mosquitoes at the release site(s). FDA ordinarily cannot acknowledge or discuss INAD files due to confidentiality concerns; however, FDA is able to do so in this case because Oxitec has publicly announced that they have opened an INAD file.

Oxitec is seeking to conduct a field trial to determine whether the release of its GE mosquito will suppress the local *Aedes aegypti* mosquito population in the release area at Key Haven, Florida. As with similar applications, FDA plans to release for public comment a draft environmental assessment submitted by Oxitec that assesses the potential environmental impacts of conducting a field trial in Key Haven with the GE mosquitoes. A field trial of the GE mosquito may only be authorized if—after a draft environmental assessment has been released for public comment and the Agency has had the opportunity to review those comments—FDA issues a final environmental assessment and Finding of No Significant Impact on the environment, or FDA prepares an Environmental Impact Statement. If such a trial is authorized and conducted, Oxitec could use the results from a field trial in an application for approval if the company decides to pursue one in the future.

Fraudulent Product Claims

Unfortunately, during emerging infectious disease outbreaks such as this, fraudulent products that claim to prevent, treat, or cure a disease rapidly appear on the market. FDA is actively monitoring for fraudulent products and false product claims related to Zika virus and will implement enforcement actions, as warranted, to protect the public health.

CONCLUSION

FDA is fully committed to remaining highly responsive and adaptive to the complex range of issues the Zika virus outbreak has presented and will continue to present. Developing the medical products necessary to help bring this outbreak under control is highly complex and will, unfortunately, take time. Close cooperation and collaboration within FDA, within the U.S. Government, with our international partners, and with product developers, is essential to help facilitate the development and availability of medical products to respond to Zika virus. There is an urgent need to accelerate medical product development programs, and FDA anticipates that—similar to the Ebola epidemic in West Africa—there will be a strong desire for access to investigational medical products as soon as they become available.

While the Ebola and Zika viruses have important differences, the response to the Ebola epidemic demonstrated that the typical, phased approach to medical product development can be accelerated and streamlined as appropriate, for the particular health circumstance; it may be appropriate in certain emergency circumstances to accept a greater than usual degree of uncertainty and risk in order to move rapidly to clinical trials, with the goal of getting safe, effective therapies or vaccine products to patients sooner. However, while greater risks may be acceptable during a public health emergency or when there is the potential for a public health emergency, the responsibility to protect patient welfare never ceases. The Ebola epidemic highlighted the importance of determining whether investigational products may help patients, do nothing, or cause unintentional harm. Thus, it is essential that clinical trials be designed to provide interpretable data—with respect to both safety and efficacy—that will enable the global community to learn whether investigational products are safe and effective for broader use.

FDA is fully prepared to leverage its authorities to the fullest extent practicable to help accelerate the development and availability of safe and effective products with the potential to help mitigate the Zika virus outbreak as quickly as the science will allow.

Thank you. I am happy to answer your questions.

Chapter 540

**TESTIMONY OF DR. THOMAS R. FRIEDEN,
DIRECTOR, CENTERS FOR DISEASE CONTROL AND
PREVENTION. HEARING ON “EXAMINING THE U.S.
PUBLIC HEALTH RESPONSE TO THE ZIKA VIRUS”***

INTRODUCTION

Good morning Chairman Murphy, Ranking Member DeGette, and members of the Subcommittee. Thank you for the opportunity to testify before you today on Centers for Disease Control and Prevention’s (CDC’s) efforts to prepare for and respond to the Zika virus outbreak, which threatens the United States and the rest of the Americas.

The Administration has requested approximately \$1.9 billion in emergency funding to respond to the Zika virus outbreak, including \$828 million for CDC, in support of both the domestic and international response, with particular attention to emergency assistance to the Commonwealth of Puerto Rico and other U.S. Territories and States with local transmission of Zika virus.

CDC is the nation’s health protection agency, working 24-7 to save lives and protect people against unpredictable threats such as the Zika virus. Nature is a formidable adversary, and Zika is our newest threat, particularly to pregnant women. CDC has some of the world’s leading experts both in diseases spread by mosquitos and in birth defects. We must act swiftly to stop the spread of the Zika virus, both domestically and globally. While we are learning more about the Zika virus every day, there are many things we do not know yet about Zika. These include our understanding of the spectrum of effects of Zika infection during pregnancy, the risk the virus may play in microcephaly, Guillain-Barré syndrome and other possible complications, the duration of Zika infectivity in semen, and determining what other factors may play a part in the consequences associated with the virus. In addition to answering these questions, we are also working to accelerate optimal mosquito control strategies, improve testing and assure preparedness for rapid detection, control, and prevention within the United States and U.S. territories.

* This is an edited, reformatted and augmented version of testimony presented March 2, 2016 before the House Committee on Energy and Commerce, Subcommittee on Oversight and Investigations.

We are making advancements in these areas and will need the additional requested funding to do so. We are figuring out more about Zika literally every day, and will share information – and adjust our guidelines and recommendations – as we learn more. That is the nature of a scientific response to an emerging health threat. The doctors, scientists, entomologists, and others at CDC are working nonstop to protect Americans from this and other health threats. We have already made significant progress identifying the Zika virus in brain tissue of affected deceased infants, developing new diagnostic tests, issuing guidance, conducting epidemiological investigations along with affected countries, and improving monitoring and surveillance in the United States including in the Commonwealth of Puerto Rico and the other U.S. territories. Much of what we know about Zika and similar viruses today is based on the work that's been done by CDC scientists. But there are still many things we do not yet know. We will continue to use the best of modern science to protect the American people. I understand that Zika virus and the emergence of serious birth defects cause concern. We are committed to providing the American people with the most accurate and timely information about Zika virus and the current outbreak.

CDC is working in collaboration with other components of the Department of Health and Human Services (HHS), including the Office of the Assistant Secretary for Preparedness and Response (ASPR) and its Biomedical Advanced Research and Development Authority (BARDA), the National Institutes of Health, and the Food and Drug Administration (FDA). We are also working with partners across the U.S. Government to communicate with travelers and health care providers, update travel alerts and clinical guidance, and develop improved mosquito-control methods.

ZIKA AND ITS HISTORY

Zika is a flavivirus, which is closely related to dengue, yellow fever and West Nile viruses. Zika virus is primarily spread to people through the bite of infected *Aedes* species mosquitos, particularly *Aedes aegypti*. The *Aedes aegypti* mosquitos, which also transmit dengue and chikungunya viruses, are extremely difficult to control. They bite during the day, indoors and outdoors, and they preferentially feed on humans. And they need only the smallest bit of water to breed – just a bottle cap is enough. The mosquitos become infected when they bite a person with Zika virus. These infected mosquitos can then spread the virus to other people through bites. Case reports of other modes of transmission include spread through sexual transmission and blood transfusion. Of great concern, Zika virus infection in a pregnant woman has been linked to issues in fetal development, and the virus has been detected in association with fatal brain malformation in newborns as well as in miscarriages.

While its adverse effects were unforeseen, Zika is not a new virus. It was first recognized in 1947 and has caused occasional illness in Africa and Asia, but the first outbreak we know of occurred in 2007 in the small Pacific island of Yap. Last May, the first local transmission of Zika in the Americas was reported in Brazil, and by the end of 2015, Brazilian authorities estimated that the outbreak there involved perhaps a million suspected cases of Zika virus. In recent months, the virus has spread rapidly throughout Latin America and the Caribbean, as well as to parts of the Pacific. As of February 18, 2016, 32 countries and territories, including

the Commonwealth of Puerto Rico, a United States Territory, the U.S. Virgin Islands, and American Samoa have reported local transmission of the Zika virus.

SYMPTOMS AND ADVERSE OUTCOMES

Many people exposed to Zika virus will have only mild symptoms - such as fever, rash, joint pain, and red eyes or conjunctivitis - that will last no more than a week. In past outbreaks, about four out of five people infected with Zika appear not to have had symptoms at all, although we do not know if that is the pattern in this outbreak.

Increasing evidence suggests that Zika virus infection may be associated with more serious health outcomes. In October 2015, Brazilian authorities recognized a concerning increase in microcephaly, which has occurred in close sequence to Brazil's outbreak of Zika virus. Microcephaly is a usually rare, serious condition where a baby's head is smaller than expected based on age and sex. Microcephaly is not a diagnosis in and of itself, but a sign that the brain did not develop as it should in the womb. Babies with microcephaly can have a range of problems, including seizures, developmental delay, feeding problems and hearing loss. In some cases these problems can be fatal.

Laboratory tests at CDC strongly suggest a link between Zika virus infection during pregnancy and microcephaly.

We do not fully understand the nature of this relationship, or if there are important cofactors. We also do not know what, if any, other outcomes might be associated with Zika infection during pregnancy among infants who do not have microcephaly. Microcephaly in infants can be devastating to the affected families, and this ongoing outbreak is concerning to everyone, especially for pregnant women, and their families who may travel to or live in the infected areas. The association between Zika virus and microcephaly is unexpected. A new infectious cause of fetal malformations has not been identified in decades. Zika virus spread in the Americas and its effect on pregnancy are developments that we are working with partners to better understand.

Our key priority at this point is to reduce the risk to pregnant women of Zika virus infection. Given the potential risks associated with maternal Zika infection, prevention is key for this response, with a parallel approach of acting based on what we know now and, at the same time, discovering more so that we can better prevent adverse health outcomes in the future. That's why, during the same week we identified Zika in brain tissue specimens from affected infants, we issued a warning to advise pregnant women not to travel to affected areas. That's why we are working intensively with the Commonwealth of Puerto Rico and other areas to get support to women who are or who may become pregnant and do what we can to reduce the threat of Zika there. And that's why we are engaging in studies with international partners so that we can more fully understand the magnitude of risk and the range of outcomes associated with Zika virus infection during pregnancy.

Health authorities in Brazil and elsewhere have also reported an increase in suspected cases of Guillain-Barré syndrome, a rare neurologic disorder in which a person's own immune system damages nerve cells, leading to nerve damage or paralysis that lasts for several weeks or several months. Most people fully recover, but it can take a few months or even years to do so. Some people with Guillain-Barré syndrome have permanent damage and, in rare cases,

people have died. It is difficult to determine if any particular pathogen “caused” or “triggered” Guillain-Barré syndrome. Currently, we do not know if Zika virus infection causes Guillain-Barré syndrome.

However, the development of Guillain-Barré syndrome is a recognized after-effect of a variety of different infections. CDC is currently collaborating with public health officials in Brazil to investigate whether there is any causal link between Zika infection and Guillain-Barré syndrome.

Domestic Activities

While we are working to better understand these health outcomes, transmission, diagnostics, and mosquito control, CDC is moving quickly to respond. We have moved our Emergency Operations Center to the highest alert level for Zika virus to further enhance our response activities in areas with current local transmission and to accelerate preparedness efforts in anticipation of local transmission in the continental United States.

For the Commonwealth of Puerto Rico as well as the U.S. Virgin Islands and American Samoa, a surge in resources is urgently needed. The population of *Aedes aegypti* mosquitos is widespread on these islands, protective environmental factors such as window screens are not as prominent, and the density of people puts people there at high risk for transmission. All three areas have already reported local Zika transmission, with Puerto Rico alone reporting at least 30 cases. Furthermore, recent outbreaks of dengue and chikungunya suggest that Zika virus may spread extensively and rapidly in these areas. CDC has deployed staff to the U.S. Virgin Islands, American Samoa, and Puerto Rico to support response activities and provide technical assistance to health departments there. CDC and the CDC Foundation are also partnering to create Zika prevention kits.

Containing educational materials, and initial supplies of prevention tools such as insect repellent, the purpose of these kits is to help pregnant women in areas with local Zika transmission protect themselves and their pregnancies. Five thousand of these kits have been dispatched to the Commonwealth of Puerto Rico, the U.S. Virgin Islands, and American Samoa; and CDC plans to distribute more than 45,000 kits to these areas in the future.

While we have not yet seen transmission of the Zika virus by mosquitos within the continental United States, we expect many returning travelers will have Zika infection. As a potential benchmark, we received reports of 3,270 travelers from 49 states with laboratory confirmed cases of chikungunya infection in 2014 and 2015. There are about 40 million people travelling between the continental U.S. and Zika-affected areas each year. Therefore, all U.S. jurisdictions must be prepared to evaluate, test, and manage patients with potential Zika virus infection, particularly pregnant women. Furthermore, *Aedes aegypti* is found in many areas of the United States, raising the risk of local transmission. The most recent data available suggest that *Aedes aegypti* are found in 13 states and *Aedes albopictus* are found in 31 states and the District of Columbia. Recent chikungunya and dengue clusters in the United States suggest that Zika outbreaks in the U.S. mainland may be relatively small and localized due to protective factors like window screens and less dense living conditions; however, any local outbreaks will be of deep concern to the people living there, and we must be prepared for different scenarios including more extensive transmission risk.

CDC is working with health departments across the country to ensure coordination and to expand capacity for detecting and responding to Zika virus. Surveillance is essential to monitor and quickly identify areas with local transmission. We conduct multi-faceted surveillance for arboviruses, including Zika, through ArboNET, an integrated network which funds, through our Epidemiology and Laboratory Capacity cooperative agreements, staff in 49 states, the Commonwealth of Puerto Rico, and six large municipalities to conduct human case investigations, collect and test mosquitos, and perform laboratory analysis on arboviruses including Zika. Zika virus is now a nationally notifiable disease, meaning states report the virus to CDC, which will aid Zika surveillance efforts. CDC is also working with several states and the Commonwealth of Puerto Rico to determine a baseline prevalence of microcephaly so that any increase, should it occur, can be quickly and accurately identified.

With support from the President's emergency request, CDC will build on its current efforts to provide financial and technical resources to states and territories through its cooperative agreements to strengthen their capacity to prepare for and respond to emerging insect-borne threats such as Zika virus. These resources may be used to help health departments expand their capability to manage cases of local Zika virus transmission in their areas and to implement community education and prevention programs to reduce human-mosquito contact and subsequently, the risk of Zika transmission. Resources will also be used to implement mosquito control strategies, including mosquito surveillance. Current mosquito surveillance capacity is uneven across the country, which makes our knowledge about the locations of the two mosquito vectors that transmit Zika virus potentially incomplete. To effectively track the spread of the outbreak, it is critical that states and territories receive specimens and test for Zika virus to diagnose and report travel-related and locally acquired cases of Zika. Under the emergency request CDC will expand its efforts to assist public-health labs nationwide to test for Zika and to provide the guidance on how to interpret test results. In addition, CDC is available to provide testing of any Zika samples upon request.

We are working to expand the number of health departments that have the ability to perform testing, but will need to increase the existing capacity to meet the projected demand for Zika testing. Given that, last year, it is estimated that approximately 500,000 travelers to areas of current Zika transmission were pregnant women and 36,000 pregnant women are currently living in the Commonwealth of Puerto Rico, the expansion of testing capacity in public health labs nationwide, included in the request, is urgently needed in order to ensure that every pregnant woman needing testing for Zika virus has access.

Recognizing the potential for Zika virus transmission through blood transfusions, CDC is collaborating with FDA to ensure the safety of the blood supply from Zika virus, particularly in regions experiencing local outbreaks.

CDC has sent experts to the Commonwealth of Puerto Rico to assess the steps needed to assure both that Puerto Rico's blood supply needs are met and that transfusion-transmitted Zika is prevented.

CDC experts are working intensively to learn more about the outbreak and provide people with the information they need to protect themselves. We will continue to issue travel alerts for the affected areas as confirmation of the virus is reported, and we'll keep the American people informed as the situation changes. We recognize people are eager for information, and our website has exceeded half a million views in recent days.

CDC has also provided guidance for doctors and other clinicians on evaluation, treatment and follow-up care of pregnant women and infants with possible exposure to Zika virus,

partnering with organizations from around the health care community to help distribute this information as widely as possible. Our guidance will continue to be updated as our knowledge increases. We have recently updated our guidance to provide recommendations for the clinical care and management of pregnant women living in areas where Zika transmission is widespread, with special consideration to the ongoing risk of maternal Zika virus infection throughout pregnancy. These guidance documents were prepared in consultation with the American College of Obstetricians and Gynecologists, the Society for Maternal Fetal-Medicine, and the American Academy of Pediatrics.

CDC also wants to ensure that the general public knows what it can do to protect itself. Pregnant women should postpone travel to regions with ongoing Zika virus transmission. If they must travel, or if they live in affected areas, CDC recommends pregnant women talk to their doctors or other healthcare providers first and strictly follow steps to prevent mosquito bites. Reducing exposure to mosquitos is important for anyone traveling to or residing in areas where the virus is circulating. Wearing long sleeves, long pants, using EPA-registered repellents such as DEET and permethrin-treated clothing (both of which are safe to use in pregnancy), and using other protections such as air-conditioning will reduce exposure to mosquito bites. Given the potential for Zika virus to be spread through sex, pregnant women and their male partners living in or who have been to Zika-affected areas should abstain from sex or use condoms for the duration of pregnancy. This is a rapidly changing situation and our understanding of the risks concerning Zika virus infection is incomplete and evolving. As we get new information, we will update our advice.

Global Activities

On February 1, the World Health Organization (WHO) declared the recent cluster of microcephaly cases and other neurological disorders (such as Guillain-Barré syndrome) and their possible association with Zika virus, a public health emergency of international concern, a reflection of the seriousness of this unfolding health threat.

CDC is coordinating its response with the U.S. Agency for International Development, as well as the Pan American Health Organization (PAHO), the regional arm of the World Health Organization (WHO), and other parts of WHO, and is collaborating with many international partners to learn more about this outbreak. We are working with the Brazilian Ministry of Health on investigation and research partnerships. Specifically, one partnership involves studying the link between Zika virus infection and microcephaly, while another is examining the relationship between Zika virus and Guillain-Barré syndrome. Research teams from CDC are also in other countries, including Colombia, to explore collaborations that will shed light on the risk of microcephaly in relation to Zika virus infection during pregnancy.

In addition, CDC is offering support to all countries so that they can test samples from microcephaly cases for serologic evidence of Zika virus infection, and CDC is helping countries throughout the Americas establish in-country diagnostic capacity. To that end, we are currently, and in conjunction with PAHO, providing training to laboratorians in South and Central America on diagnostic tests, including two recent workshops in Brazil and Nicaragua.

CDC's Central American office has also facilitated the verification of Zika cases in several countries throughout Latin America, including Colombia, Venezuela, and Nicaragua.

At the request of the Department of State's Bureau of Medical Services, staff from CDC's Global Disease Detection Center in Guatemala has been involved in communication efforts to ensure that new information regarding Zika virus and its possible link to birth defects is communicated to U.S. Mission Health Unit staff throughout the Americas.

The Global Health Security Agenda, with critical support from Congress, is collaborating with countries around the world so that we can find, stop, and prevent health threats when and where they first emerge. Zika has been present in Africa for decades, and it's possible that it could become linked to microcephaly there as well. The sooner we detect a problem, wherever it occurs, the more rapidly we can respond to it and prevent it from spreading. It is in all of our best interests to work with others to improve public health capacity around the world.

IMPROVING THE TOOLS AND INFORMATION FOR RESPONDING TO ZIKA

We need a better understanding of the epidemiology of Zika and potential Zika-associated birth defects and other adverse health outcomes. We need better diagnostic methods that can quickly and clearly differentiate between similar viruses to detect evidence of past Zika infection. Testing for current Zika infection is only reliable in the first week of illness. A Reverse Transcription-Polymerase Chain Reaction (RT-PCR) test can provide a definitive diagnosis of Zika, but only if it is performed within about seven days of symptom onset. The tests we have available for Zika in persons who are no longer ill may have cross-reactivity with similar flaviviruses, particularly dengue, which can lead to false-positive or inconclusive results and confirmatory testing is required. Diagnosis is particularly challenging with Zika virus since most people will not experience symptoms. We also need to determine how long a man who has been infected with Zika may continue to be able to sexually transmit the virus to a partner, and we need better tools to screen the blood supply.

We also need to advance our ability to control the mosquito population. Existing methods for mosquito control all have shortcomings, especially in areas where the population of *Aedes* mosquitos is rampant. Furthermore, in some areas like the Commonwealth of Puerto Rico, mosquitos may have developed resistance to certain insecticides, which could reduce the range of substances that can be used to effectively decrease mosquito populations. We need to implement the best tools we have today, improve current vector control strategies, and identify better options. We also need better mosquito surveillance to determine the location of mosquitos and areas with mosquito resistance to insecticides, which would inform the implementation of new mosquito control techniques.

Finally, a vaccine is needed to protect people at risk of Zika virus infections, particularly preventing infection among women of childbearing age. At CDC, our scientists developed both a West Nile virus vaccine, which is currently in use for animal protection in the United States, and a dengue vaccine, which is currently in clinical trials. The President's request will increase Zika research, improve diagnostics and support advancements in vector control methods. Although availability of a licensed Zika vaccine is several years away, we do not know how long Zika will be a problem in the Americas nor whether the mosquito control efforts that must be implemented will yield durable results.

CONCLUSION

Microbes continue to be formidable adversaries. To protect Americans, the Zika emergency request invests in the laboratories, disease detectives, disease tracking systems, mosquito control, and investigations needed to continue to improve these essential tools.

The emergence and reemergence of health threats, including those spread by mosquitos and other vectors is not a unique event but something we expect to continue to see in the future. These outbreaks cannot be expected to occur in isolation of one another. The Commonwealth of Puerto Rico and Hawaii were already responding to outbreaks of dengue when Zika virus arose as an urgent health threat. We need to address the threat of mosquitoborne diseases systematically, rather than episodically. Thank you again for the opportunity to appear before you today. I appreciate your attention to this concerning outbreak and I look forward to answering your questions.

Chapter 541

**TESTIMONY OF LAWRENCE O. GOSTIN,
FACULTY DIRECTOR, O'NEILL INSTITUTE FOR
NATIONAL AND GLOBAL HEALTH LAW. HEARING ON
“EXAMINING THE U.S. PUBLIC HEALTH RESPONSE
TO THE ZIKA VIRUS”***

EXECUTIVE SUMMARY

Following the 2014/15 Ebola epidemic, the World Health Organization (WHO) was widely criticized for its delay in taking decisive action and leadership to protect global health. Four international panels found that the WHO unreasonably delayed declaring Ebola a Public Health Emergency of International Concern (PHEIC) to call the international community to action in providing financial and technical resources for the global health humanitarian and security threat posed by Ebola.

The WHO appeared to learn from the Ebola experience. On February 1st, 2016, the Director-General, Margaret Chan, declared the clusters of microcephaly and neurological syndromes (including Guillain-Barré Syndrome) associated with Zika virus infection a PHEIC. The link between Zika virus infection and microcephaly and Guillain-Barré Syndrome is not yet proven, although suspected. Now the international community, including the United States, must answer the call to action to ensure global health security and equity against the risk posed by the spread of Zika virus.

As the only developed country in the Americas with the *Aedes aegypti* mosquito, the United States bears not only a unique responsibility to take leadership for global health in our region, but also to protect the health of United States residents. The Zika virus is already embedded in Puerto Rico, and it is likely that by the summer time there will be local transmissions in Florida and the Gulf Coast. During the summer, the *Aedes aegypti* mosquito has been observed as far north as Washington, DC,¹ and the *Aedes albopictus* mosquito, believed to also transmit the Zika virus, is found in at least 32 states in the United States.²

* This is an edited, reformatted and augmented version of testimony presented March 2, 2016 before the House Committee on Energy and Commerce, Subcommittee on Oversight and Investigations.

As Ebola demonstrated, the health security of the United States is intrinsically tied to ensuring strong health systems and a coordinated international response at the source of the outbreak. Furthermore, as a global leader for humanitarian action, the United States can provide the financial and technical resources necessary to address the Zika epidemic and protect global health. The work of the United States military and the Centers for Disease Control and Prevention (CDC) during Ebola proved to be transformative. The Ebola response was made possible by a special appropriation during the height of the epidemic, as requested by the President and allocated by Congress.

I fully support President Obama's FY2016 emergency supplemental appropriations request of \$1.86 billion to respond to the Zika virus domestically and internationally. This must be in addition to existing global health security funding – including unobligated Ebola funding – to ensure flexibility to respond to the United States' needs as we progress towards Summer and the threat of domestic mosquito-borne transmission.

The Global Response to the Zika Epidemic

I have served on several high-level panels reviewing the WHO and international community's response to the 2014/15 Ebola outbreak including on the Harvard-London Hygiene and Tropical Medicine Independent Panel on the Global Response to Ebola and the National Academy of Sciences Global Health Risk Framework Commission. I also closely advised the United Nations Secretary General's High Level Panel on Global Health Crises. The WHO's failure to act quickly and decisively cost thousands of lives.³ Of particular concern was the unreasonable delay in the convening of an Emergency Committee to advise to the WHO Director-General whether she should declare the Ebola outbreak a Public Health Emergency of International Concern (PHEIC) under the International Health Regulations (2005). The Director-General was also late in mobilizing the international financing needed to prevent international spread of the Ebola Virus.

Despite these critiques from numerous independent panels as well as implementing internal reforms, the WHO delayed taking its leadership role in response to Zika. The CDC and Pan American Health Organization had been working actively on Zika, in collaboration with the Brazilian government for months prior to the WHO's active engagement. Given the broad, global distribution of the mosquitoes that transmit Zika virus, and in the absence of rapid diagnostic tests or a vaccine, on January 27, 2016, my colleague Daniel Lucey MD and I called for the WHO to not repeat its mistakes from Ebola, and for the WHO Director-General to immediately convene an Emergency Committee on Zika virus to assess whether a PHEIC should be declared.⁴ On January 28, 2016, the WHO announced that the Director-General would convene an Emergency Committee on Zika virus and the observed increase in neurological disorders and neonatal malformations.⁵

Following this announcement, the WHO acted decisively and with leadership. On February 1st, 2016, the WHO Director-General Margaret Chan declared the clusters of microcephaly and neurological syndromes including Guillain-Barré Syndrome a PHEIC.⁶ This was the fourth PHEIC the WHO Director-General has declared since the International Health Regulations (2005) came into effect in June 2007, including for Influenza A (H1N1), polio, and Ebola.⁷ While a causal relationship between these clusters and Zika virus is

strongly suspected, it is not yet scientifically proven. Nonetheless, the declaration of a PHEIC reflects the pressing need for the coordination and resourcing of international efforts to address the Zika epidemic.

Accompanying the PHEIC, the Director-General issued temporary recommendations to countries on handling the Zika epidemic. While not legally binding, these temporary recommendations have significant normative weight and are issued in accordance with the legally binding International Health Regulations (2005). The recommendations advise countries to enhance surveillance for Zika virus infections, develop diagnostic tools, communicate the risks of Zika virus infection, aggressively implement vector control and personal protective measures, and ensure reproductive health services, including access to contraception (including emergency contraception) and maternal health care.

On February 16th, 2016, the WHO released its “Zika Strategic Response Framework & Joint Operations Plan”.⁸ This plan is a critically important step towards an effective response to the Zika epidemic. It is also a critical step towards re-establishing the WHO’s global health credibility which was significantly undermined during Ebola. The plan estimates that \$56 million will be required for the Zika epidemic response.⁹ The majority of the funding is for risk communication and community engagement (\$15.5 million) and care for those affected (\$14.2 million). Given the vital role that the Pan American Health Organization (PAHO) plays in leading the global health response in the Americas, a large amount of the funding under this plan is appropriately earmarked for PAHO (\$8.1m), including \$1.5 million for surveillance and \$2.25 million for vector control measures. Yet, despite this estimate of the needs, the WHO has yet to mobilize the required funding. That is still another reason to support the President’s proposed emergency Zika appropriation.

While the WHO’s commitment to raising funds needed for the global response is positive, the estimate of \$56 million is far less than that required to stem the Zika epidemic in the Americas.

Major global funding is needed for aggressive mosquito control, surveillance, and research. Under the WHO’s plan, the overall estimates for these strategies are \$6.4 million, \$7.1 million, and \$6.4 million respectively. The Zika epidemic is likely to spread to many regions of the world beyond the Americas, which will require considerably greater funding. During the Ebola outbreak, the WHO released financing estimates that were far from adequate, requiring repeated increased cost estimates as the Ebola outbreak unfolded. Overly conservative estimates for the Zika epidemic response could result in the same mistakes seen with Ebola: waiting until a global emergency to mobilize funding will always be too little, too late. The WHO must have access to a much larger emergency contingency fund. The trigger for use of this fund would be the declaration of a PHEIC.

The Global Health Risk Framework Commission (on which I served) estimated that it would cost \$4.5 billion annually to truly reduce pandemic risks.¹⁰ While this may appear to be a great deal of money, it pales in comparison to the global costs of a pandemic. Previous epidemics have demonstrated that states with major emerging disease outbreaks experience a loss in GDP of up to 10%. Brazil is may experience a similar economic impact with the upcoming 2016 Olympics and Paralympics in Rio de Janeiro. The World Bank has advised that while initial estimates of the short-term economic impact of the Zika epidemic in the Latin American and Caribbean region is 0.06% of GDP, such estimates are based on a swift, coordinated international response. The World Bank however advises such estimates could be significantly larger given the high dependence on tourism in the region if the virus is not

promptly contained, if a causal association between Zika virus and clusters of microcephaly and Guillain-Barré Syndrome is established, and if public perceptions of the risks of Zika change.¹¹

In addition to the financial and technical resources dedicated by the WHO, it is vital that the WHO use its normative power for global public health. The WHO was criticized for prioritizing politics over public health during the Ebola outbreak. It must not let the same happen with the Zika epidemic, which disproportionately burdens women and the poor. In particular, calls by governments that women avoid getting pregnant – including Brazil, Honduras, Colombia, and El Salvador – without providing access to reproductive health and rights services, are not only ineffective but also unfair to women. In Central and South America, there is limited access to contraception – especially in poorer communities most at risk of Zika virus infection and cultural and religious norms still restrict the availability and use of contraception. Nearly all countries in the Americas currently experiencing or likely to experience Zika virus cases have laws preventing women from accessing reproductive health services such as emergency contraception and abortion. In addition, the quality, accessibility, and affordability of maternal health care systems vary greatly between and within countries, with varying degrees of post-partum support services for children born with disabilities. Pope Francis recently supported the expanded use of contraception in the face of potential harms to pregnant women from Zika virus infection.

Both the WHO and the international community's response to the Zika epidemic must therefore be comprehensive, equitable, and substantial.

The United States' Domestic Response

The Risk to the United States

The mosquitoes that transmits Zika virus – *Aedes aegypti* (primary vector) and *Aedes albopictus* – is present in the United States and its territories.¹² One recent study modeling possible Zika spread estimates that more than 60% of the US population lives in areas conducive to seasonal Zika virus transmission,¹³ with Florida and Southern Texas at risk of year round transmission. The United States is the only high-income country in the Americas at risk of local Zika virus transmission.¹⁴ As a result, the United States domestic response must cover not only returning travelers who may be infected and local transmission of Zika virus from sexual intercourse, but also local transmission of Zika virus due to infected mosquitoes.

On February 3, 2016, the CDC's Emergency Operations Center (EOC) moved into Level 1 activation to accelerate domestic preparedness in anticipation of local Zika virus transmission by mosquitoes in the Continental United States.¹⁵ Level 1 is the EOC's highest level of activation, reserved for critical emergencies. This involves assignment of the largest number of staff possible to work on a response. There have been three previous EOC Level 1 responses: the Ebola outbreak, Influenza A H1N1 outbreak, and Hurricane Katrina. Moving to this level of response demonstrates the importance of preparedness for the Zika outbreak and supports the development of laboratory tests to diagnose Zika infection, studies to investigate the association between Zika virus and microcephaly and Guillain Barré

syndrome, surveillance in the United States and its territories, and support of efforts in Puerto Rico, Brazil, and Colombia.

Travel Advisories and Restrictions

The CDC has issued Level 2 (Alert: Practice enhanced precautions) general travel advisories for Zika virus in areas with local transmission such as South America, Central America, Mexico, Pacific Islands, and the Caribbean.¹⁶ In addition, these Level 2 travel alerts include specific interim recommendations that pregnant women should consider postponing any travel to affected regions. The CDC has not issued any Level 3 (Warning: Avoid all non-essential travel) travel advisories which would indicate danger to all travelers, not only travelers with specific risk factors, such as pregnancy.

Travel advisories are important for ensuring that individuals traveling to Zika virus affected countries have adequate information to decide whether to travel and what steps they should take to prevent Zika infection while in affected countries and upon return to the United States. Given the typically mild symptoms of Zika virus in healthy, non-pregnant individuals, Level 3 travel warnings are not currently warranted. Priority should be given to continuing the current information sharing process to travelers on how to prevent mosquito bites, such as through the use of EPA-registered insect repellents, the covering of exposed skin, and sleeping in screened or air-conditioned rooms, and how to prevent possible infection of pregnant partners through sexual intercourse upon return to the United States.

Notably, the CDC and WHO have different advice to pregnant women traveling to Zika affected countries. The CDC's response is more proactive and one that I strongly support.

Travel bans are not warranted, including specific bans for pregnant women at any stage during pregnancy, which would be unnecessarily discriminatory and intrusive. It is important that the CDC is supported in its efforts to set, continually review, and update travel advisories as the public health circumstances change. The WHO Director-General's temporary recommendations issued with the PHEIC declaration specifically advise against travel or trade restrictions to prevent the spread of Zika virus.

Quarantine and Isolation

As a vector-borne disease, Zika virus is predominately transmitted through the bite of an infected female *Aedes aegypti* mosquito. In addition, most individuals infected with Zika do not show symptoms, making identification of individuals for isolation very difficult. The quarantine of persons suspected of Zika virus infection, or isolation of persons with Zika virus infection, is therefore not an effective or warranted public health strategy. While there is evidence of sexual transmission of Zika, this mode of transmission would also not be favorable to quarantine or isolation measures. As a result, the use of quarantine and isolation in response to Zika is unfounded and therefore likely to be considered an unreasonable and unnecessary burden on individuals' liberty that does not have justification in public health. In the temporary recommendations issued with the PHEIC, the WHO Director-General has advised against restrictions such as quarantine and isolation to prevent the spread of Zika virus. Control efforts should therefore focus on mosquito eradication, education about the measures individuals can take to protect themselves from infection, and funding the development of a vaccine.

Vector-Control

It is a public health priority that the main source of Zika virus transmission — principally the *Aedes aegypti* mosquito — is subject to aggressive vector control efforts. In addition to the physical removal of stagnant water that serves as mosquito breeding sites, the use of safe, effective and approved insecticides is necessary. However, insecticide resistance is growing and the WHO is investigating novel mosquito control strategies, such as the use of transgenic mosquitoes to reduce local mosquito populations.¹⁷

Given the public health impact of the *Aedes aegypti* mosquito, I support the watchful use of transgenic mosquitoes through a carefully controlled release that monitors the effects on mosquito-borne diseases — including Zika, Dengue, and Chikungunya viruses — as well as any potential ecological harms. Trials so far have demonstrated promising results in drastically reducing local mosquito populations that carry these diseases without causing other harms. There is also little evidence that transgenic mosquitos cause ecological harms, although potential harms need to be closely watched and controlled for.

Ensuring Equity and Justice in the United States' Health System

Given the disproportionate impact of the Zika epidemic on women, it is essential that women in the United States are guaranteed access to reproductive health services including contraception, emergency contraception, and maternal healthcare. Where it is lawful, pregnant women with a fetus known to have microcephaly should be offered the opportunity to abort the pregnancy.

Given the possible sexual transmission of Zika virus, condoms must be readily available and accessible to both men and women in the United States. In addition, concerns about fetal health cannot stop at birth: infant, child, and ongoing healthcare and support services for babies that may be affected by the Zika epidemic must be guaranteed. The Federal and States Governments must act to protect the health of US citizens, and meet their obligations under international health and human rights law.

Ensuring Financing for Response Efforts: President Obama's Supplementary Funding Request

On February 22nd, 2016, President Obama submitted a FY 2016 emergency supplemental appropriations request of \$1.86 billion to respond to the Zika virus domestically and internationally.¹⁸ The vast majority of this funding request is directed to the Department of Health and Human Services — \$1.48 billion, \$828 million of which is directed to the CDC. This funding includes \$200 million to support the development of a vaccine through to commercialization with the National Institutes of Health and product development and approvals with the Food and Drug Administration. The United States Agency for International Development (USAID) would receive \$335 million for targeted activities in South America, Central America, and the Caribbean. Finally, \$41 million would be directed to the Department of State to *inter alia* support WHO, PAHO, and UNICEF public health efforts to address the Zika virus in affected countries while ensuring United States health security. Given the unknowns of the health humanitarian and security risk posed by Zika — especially as we transition to Summer — this funding is essential to ensure flexibility to respond to the United States' needs, including beyond that already identified.

Use of Unobligated Ebola Emergency Funds for the Zika Response

While it may seem appealing to use money previously allocated to the Ebola outbreak, such a move risks making the United States more vulnerable to infectious disease threats. Failure to develop and secure health systems in developing countries – whether in West Africa or South America – risks the health, safety, and security of the United States.

Ensuring global public health is not simply about a rapid response, but a sustainable response. Reallocating money from one infectious disease outbreak to another undermines efforts to ensure surveillance, detection, response, and control strategies are not only operational but sustainable in countries at risk of outbreaks. While infectious diseases may appear quickly, the efforts to prevent and respond to them cannot simply be about extinguishing fires, but rather preventing them from flaring up and occurring again in the future. Given the economic impact of outbreaks, sustainable and systems-wide technical and financial resources are essential to ensure taxpayers' money is utilized effectively. Furthermore, reallocating money from one infectious disease outbreak to another infectious disease outbreak risks the long-term health, safety, and security of the United States. It is important to note that the USAID funding request in President Obama's FY2016 emergency supplemental appropriations request would provide flexibility in the use of remaining USAID Ebola funds.¹⁹

Global health security and public health is grossly underfunded. I strongly advise that the Zika supplementary budget request is funded independently from unobligated past emergency funds.

Chapter 542

EPIDEMIOLOGICAL CONCEPTS, PUBLIC HEALTH AND Q FEVER

Alexandra Müller*, PhD and Eduarda Gomes-Neves, PhD

ICBAS-UP, Institute of Biomedical Sciences Abel Salazar; CECA-ICETA,
Centre of Studies of Animal Science, University of Porto, Porto, Portugal

ABSTRACT

In this chapter, we define epidemiological concepts commonly used when describing zoonotic infectious diseases and relate these to Q fever. The aim is to promote the understanding of the remaining chapters, in particular for readers less familiarized with epidemiological and biomedical terminology. After a brief description of the epidemiology of coxiellosis, the distinction between infection and disease is highlighted, as only a proportion of *Coxiella burnetii* infections result in clinical disease in humans and animals. Q fever is considered a zoonosis, i.e., an infection/disease naturally transmitted between vertebrate animals and humans. A key characteristic is that once transmitted to humans, the *C. burnetii* infection dies out quickly as human host populations are inefficient in maintaining the transmission chain. Q fever has been coined an emerging or re-emerging disease on one hand, and a neglected zoonosis on the other. The emergence of coxiellosis may in some cases be genuine, and in others partly be explained by higher awareness rather than by true emergence. Disease emergence can be driven by multiple factors such as pathogen and host characteristics, population dynamics, ecological and environmental factors. The ability to infect multiple hosts seems to be determinant. This is the case of *C. burnetii*, which is a generalist agent that can infect many species, including wildlife, reptiles, fish, birds and ticks. Interestingly, despite *C. burnetii* being a multi-host pathogen, important species-specific particularities exist regarding the transmission and pathogenesis in humans and ruminants. Regarding disease occurrence, Q fever may be sporadic, endemic or epidemic, depending on the presence of specific risk factors. Due to the potentially large impact of major outbreaks, Q fever is a notifiable disease in many countries. Despite recommendations of notification at international level, national legal frameworks vary and notification is not compulsory in all countries. Some examples of Q fever case definitions for reporting

purposes are given. The development of surveillance systems in human and animal populations is considered desirable, although challenging, as nonspecific clinical signs may lead to underreporting and because *C. burnetii* is a multi-host pathogen. The impact of Q fever on public health, e.g., measured in DALY's or by economic assessments, may change quickly from very low in endemicity to very high during major outbreaks, as illustrated here by some examples.

Keywords: epidemiological concepts, public health, reservoirs, surveillance, transmission

INTRODUCTION

In this chapter, we define epidemiological concepts commonly used when describing (zoonotic) infectious diseases and relate these to the disease. We present a brief description of the epidemiology of coxiellosis and then illustrate issues regarding the transmission, types of hosts, factors which drive the emergence of disease, detection, case definitions, monitoring and surveillance, and the assessment of public health impact of Q fever.

This chapter aims to promote a better understanding of other more specialized chapters of this book, especially for readers who might be less familiarized with epidemiological and biomedical terminology.

BRIEF DESCRIPTION OF THE EPIDEMIOLOGY OF COXIELLOSIS

Details on the infection and the disease itself can be found in the scientific literature [1–4] as well as in this book. Briefly, infection with *Coxiella burnetii* in animals is widespread in many husbandry systems and countries throughout the world. Domestic ruminants, in particular goats and sheep, are considered the main reservoirs [2]. The occurrence of the clinical form of coxiellosis in small ruminants is not easily detectable or is sporadic, although outbreaks with severe economic impact may occur. Disease in ruminants is characterized by reproductive disorders such as abortions in late pregnancy. High loads of infectious *C. burnetii* are shed by infected animals in birth products and aborted fetuses, and less so in milk and faeces [2, 5, 6]. Excreted *C. burnetii* are highly resistant in the environment and may become aerosolized. Humans may become infected via the inhalation of contaminated aerosols. Most cases of infection in humans result from spillover of *C. burnetii* infections from domestic small ruminants, as transmission between humans is not a feature [3].

Risk factors for zoonotic transmission may vary and include proximity between animal and human populations, farm management and husbandry factors such as the seasonality of parturition and specific climatic conditions, among others [2, 6]. The role of foodborne transmission, environmental persistence, and wildlife or tick reservoirs as sources of infection in humans is considered minor [2]. Exposure of susceptible humans to *C. burnetii* may result in infection and, in only a proportion of individuals, in disease. Q fever clinical symptoms in humans may be classified as acute or chronic [1, 2, 4, 7]. Symptoms of acute Q fever are usually non-specific and often relatively mild, mainly related to fever and headache, but severe disease such as pneumonia and hepatitis may occur. Risk groups such as pregnant women, immunocompromised patients and those with pre-existing cardio-vascular

conditions, have an enhanced risk of serious clinical manifestation, as well as of developing chronic Q fever [1, 7–9]. The main presentation of chronic Q fever is chronic fatigue and endocarditis. Human Q fever cases and outbreaks have been controlled by treating human cases with antimicrobial therapy and by implementing different disease control measures on farms [2, 10].

To bring the essence of a complex disease such as Q fever into one concise sentence is a challenge. Q fever has been described as “disease of humans, caused by *C. burnetii*, and a large range of animals can be infected” [3], “bacterial zoonosis, caused by the intracellular bacteria *C. burnetii*” [11], “a zoonotic disease caused by the ubiquitous pathogen *C. burnetii* responsible for acute and chronic clinical manifestations” [1], “zoonosis with many manifestations” [12], and many others. Common terms such as infection, disease, reservoir, risk factor, host and zoonosis arise in the descriptions of Q fever, warranting definitions, explanations and sometimes reflections.

INFECTION AND DISEASE

Infection is said to occur when infectious organism invade a host, and multiply within it [13]. Infections may remain localized in a particular tissue or organ, or they may spread to distant tissues/organs, causing a disseminated infection. But not all infections automatically result in what we denominate disease. Defining health and disease is not straightforward [14, 15]. Disease may be described as “any departure from health” or “any impairment that interferes with or modifies the performance of normal functions” [16], or “clinical consequences, whether mild or severe” [13]. So, some infections remain asymptomatic or subclinical, whereas others result in “overt disease,” i.e., the infections become symptomatic or clinical. In asymptomatic infections, despite replication of the agent within the host, the interference within it is too mild to induce perceivable signs or symptoms, i.e., the host remains apparently healthy and the infection goes unnoticed, but the host may still transmit the infection to others. On the other hand, in symptomatic infections, the interference with the normal structure or function of a tissue or organ is large enough to induce signs or symptoms that are clinically apparent. This may lead to (veterinary) medical attention seeking and further diagnostic investigation. When talking about symptoms and clinical signs, one has to bear in mind that a symptom is a subjective feeling or perception, whereas a clinical sign is something that can be observed or measured objectively by others. Therefore, in the context of human medicine, both, clinical signs and symptoms are commonly referred to, whereas strictly speaking, only clinical signs are described for animals.

Within the context of Q fever, the line between infection and disease may become blurred. Sometimes the term Q fever is used to specifically describe in humans [3, 4, 17]. On other occasions, the term is extended to describe disease occurrence in animals [2, 18, 19]. And sometimes the distinction between infection and disease becomes less clear and the term Q fever is also used to describe asymptomatic infections by *C. burnetii* [20]. These slight variations in the terminology on Q fever and coxiellosis are common, as universally accepted definitions are lacking, despite trends of harmonization mostly for reporting purposes [5, 19, 21]. The reader is thus invited to keep an open mind when reading on the subject.

TRANSMISSION OF ZOONOSES

Q fever is considered an infectious disease because it is caused by an infectious agent. But is *C. burnetii* also a contagious or communicable disease, i.e., is it transmissible? Transmission of infection or infectious agents from an infected to a susceptible individual may occur by direct or indirect contact [13, 22]. Direct contact requires close proximity, and may occur, for example, by the respiratory or oral route, whereas indirect contact may occur by vectors, contaminated objects or the environment. Indirect transmission involving widespread contamination of the environment may provide more opportunities to infect different hosts, than direct contact [23]. Many pathogens can be transmitted by more than one route. *C. burnetii* can be transmitted by both, direct transmission - predominantly by the respiratory route - and indirect transmission - by exposure to contaminated environment or ticks [1].

Regarding the sources of infectious agents, diseases may be classified as anthroponoses or zoonoses, according to whether the pathogens are predominantly transmissible from human to human or between animals and humans, respectively. The term sapronose is used for agents which can replicate in the environment, and from where they can infect humans [24, 25]. Q fever is considered a zoonosis, defined as any disease that is transmitted from animals to humans, or vice versa [26]. It is neither an anthroponosis nor a sapronosis, as it does not readily transmit between humans, nor is it capable of replicating in the environment, despite being able to survive for weeks in the environment. Within zoonoses, a further distinction can be made according to the predominant direction of transmission. Anthropozoonoses are those where the disease or infection spreads from animals to humans, whereas with zooanthroponoses the spread is the other way round [25, 26]. This distinction is not recommended anymore and the term zoonosis should be preferentially used to describe any disease or infection that is naturally transmissible between vertebrate animals and humans [2, 5, 25, 27]. One important feature of several zoonoses, including Q fever, is that once transmitted to humans, the infection dies out quickly, as human host populations are rather inefficient in maintaining the transmission chain [25, 28].

EMERGING, RE-EMERGING AND NEGLECTED ZOONOSES

An emerging zoonosis or pathogen can be defined as “a pathogen that is newly recognized or has newly evolved, or that has occurred previously but shows an increase in incidence or expansion in geographical, host or vector range” (see www.who.int/zoonoses/emerging_zoonoses/en). On the other hand, a re-emerging pathogen is one whose incidence is increasing in an existing host population as a result of long-term changes in its underlying epidemiology [24, 29]. Pathogens may sometimes be labelled as emerging grounded on subjective criteria, or associated to increased awareness, improved diagnosis, characterization of previously unrecognized aetiological agents, and the interests of researcher, as much as any objective epidemiological data [24]. The majority of emerging and re-emerging human pathogens (>75%) are zoonotic [24]. Of these over 71% have wildlife origins [29].

Zoonotic pathogens are almost twice as likely as non-zoonotic pathogens to be regarded as emerging. They are not strongly associated with any particular reservoir species, but can be associated with both, the taxonomic and ecological amplitude of host range [24]. Transmissibility between humans is a risk factor for the emergence of zoonotic pathogens. We have a poorer understanding of the epidemiology of multi-host pathogens than simpler single-host systems. This scarcity of understanding is a particular problem with emerging diseases, since most emerging human, domestic animal and wildlife diseases infect multiple hosts. Reservoirs should be defined with reference to particular target populations [30].

Through constant modifications in human and animal demographics, such as the intensification of farming and concentration of animals, as well as environmental fluctuations, new and recurring diseases are likely to continue to emerge [29, 31]. They may also be classified as opportunistic, since the opportunity of spread to human hosts may rise due to factors such as changing patterns of lifestyle, farming, transportation, etc. [24, 29, 32]. Since more resources are allocated to disease-related research and treatment in the northern hemisphere, the number of hosts and pathogens “discovered” in these countries tends to increase [32–34]. In the case of Q fever the number of publications on outbreaks has been growing since 1999. This increase may reflect a higher attentiveness to the disease rather than a true emergence. The so called re-emergence of Q fever could be explained by an enhanced vigilance and the increased dedication of more resources to the improvement of the diagnosis for which serological and PCR tests allow an accurate detection of the infected flocks [35].

Q fever has been coined an emerging or re-emerging disease [35, 36] on one hand, and a neglected zoonosis on the other [20, 37, 38]. The concept of neglected zoonosis is commonly associated with poverty, disproportionately affecting neglected populations and less developed countries [29, 37, 39, 40]. However, Q fever can also be termed a neglected zoonosis in the sense of underdiagnosis and underreporting due to lack of awareness or lack of surveillance systems [20].

DRIVERS OF DISEASE EMERGENCE

Several factors have been proposed to explain disease emergence, including pathogen characteristics (mutation, recombination and genetic drifts), host characteristics (immunosuppression), host population characteristics (population size, behaviour and movements) and ecological and environmental factors (land use, changes in agriculture, deforestation and urbanization) [24, 41]. Within pathogen characteristics, the ability to infect multiple hosts seems to be determinant, since multiple host pathogens are very prevalent among human pathogens (61.6%), even more among domestic mammal pathogens (livestock 77.3% and carnivores 90.0%) [30, 32]. Host range and biodiversity are also associated with disease emergence, since more zoonotic host species are expected to occur in regions with high biodiversity. Nevertheless, in terms of emergence, the majority of human infectious diseases appeared for the first time in northerly latitudes, with a hotspot in Europe [32].

The reservoir species also play an important role in the emergence of zoonosis. Ungulate reservoirs of zoonotic disease have been of particular interest because of high human contact rates through hunting, and the degree of contact or relatedness between wild and domesticated species (livestock). The time since domestication correlates positively with the number of

zoonotic infections shared between ungulates and humans, and the fact that species with the longest history of domestication carry more zoonotic pathogens and also may transmit infection to a greater diversity of alternative host species [32]. Many zoonotic pathogens fall into the category of generalist agents exhibiting extensive host diversity. *C. burnetii* is a good example as it can infect hosts ranging from domestic animals to wildlife, reptiles, fish, birds and ticks.

TYPES OF HOSTS AND RESERVOIRS

C. burnetii is a generalist or multi-host pathogen [2, 5, 19, 29]. And, generally speaking, the epidemiology of these pathogens is complex [30, 42]. Despite *C. burnetii* being able to infect multiple species, interestingly, important species-specific traits exist regarding transmission and pathogenesis. As described above, transmission occurs predominantly from animals to humans. Transmission between certain animal species, in particular ruminants, occurs readily, whereas between humans it does not, i.e., the infection cycle can be more efficiently maintained within certain animal populations such as ruminants, but less between others. Consequently, in the context of Q fever, ruminants are considered the maintenance (reservoir) hosts, whereas humans are considered accidental (incidental hosts or dead-end hosts). Incidental (accidental or dead-end hosts) are those that can be infected, but usually do not further transmit the infection [22].

Sometimes a distinction is made between the terms maintenance host and reservoir. A maintenance host, also denominated primary or natural host, is a species which can maintain an infection in an area, whereas in a reservoir host, the agent multiplies and represents a common source of infection for others [22]. However, frequently, both terms are used interchangeably. For example, small ruminants can be considered maintenance hosts or reservoirs for *C. burnetii*, as their abortions are an important source of environmental contamination and/or direct transmission to other animals or humans [19, 20]. More recently and within the context of generalist or multi-host pathogens, the term reservoir has been subject to discussion and redefinition, moving away from the single-species single-host concept, and allowing for interaction between multiple species and also the environment. Haydon et al. [30] defined a reservoir as “one or more epidemiologically connected populations or environments in which the pathogen can be permanently maintained and from which infection is transmitted to the defined target population.” According to Ashford [43], the above definition implies that the reservoir includes all hosts equally, irrespective of its role in transmission to the target host and argues that incidental and maintenance hosts should be considered differently. He refined the definition of reservoirs of infection as ecologic systems that include all different host populations, environmental components, as well as quantitative requisites such as critical community size, necessary to maintain the agent indefinitely. The reservoir for *C. burnetii* can thus be seen as the ecologic system that includes different host species (e.g., ruminants as maintenance hosts and humans as incidental hosts), an environmental compartment (e.g., resistance in the environment and easy spread by the windborne route) and critical community size (e.g., herd size, and geographical proximity between farms and human settlements) [23, 44–46].

The term pathogen spillover also is frequently used in the context of Q fever, and other emerging infectious diseases. Spillover is said to occur when transmission from a reservoir population to a given (incidental) host population leads to epidemics [32, 41, 47]. Q fever epidemics in humans are a good example of spillover infections from infected sheep and goats to humans [2, 48].

Summarizing, *C. burnetii* it is a multi-host pathogen with an environmental component [20, 28]. Domestic goats and sheep (also cattle) are considered maintenance hosts, as they maintain infection by excreting high numbers of bacteria, especially during abortions. Resistance of the agent allows survival in the environment. Other susceptible hosts such as horses, cats, birds and ticks, as well as humans, may get infected either by direct contact with infected goats or by indirect contact (inhalation) with aerosolized particles from the environment. These are considered dead-end hosts, and infection is said to occur by spillover from maintenance hosts.

DISEASE OCCURRENCE: SPORADIC, ENDEMIC AND EPIDEMIC

Depending on the context, the occurrence of Q fever can be described as sporadic, endemic or epidemic. An infection or disease is said to be endemic when it occurs regularly [13, 22]. Q fever (*C. burnetii* infection) is often described as being endemic in ruminants [49–51]. After infection, whether symptomatic or asymptomatic, animals and humans mount a humoral immune response, i.e., antibodies specific to *C. burnetii*, and these persist for many months or years and can easily be measured [10, 52, 53]. If a high proportion of animals have antibodies to *C. burnetii*, i.e., seroprevalence is high, it is inferred that the agent is circulating and consequently that the infection is endemic [10, 20, 49, 54].

On the other hand, outbreaks or epidemics are said to occur when there is a sudden increase in frequency of disease above endemic levels [13, 22]. These terms typically are related to the occurrence of disease – either in animals and/or in humans - and not solely to infection [10, 23, 55, 56]. Disease or outbreaks may occur sporadically, i.e., irregularly and haphazardly in single animals of a single farm, or they may occur in clusters of animals/farms more or less prolonged in time, such as the 2007-2010 outbreak in the Netherlands [3, 5, 22, 49].

DETERMINANTS OF DISEASE OR RISK FACTORS

How can it then be explained, that despite infection by *C. burnetii* being so widespread, the disease occurrence in animals as well as in humans is mostly only sporadic? And why does it sometimes, but not always, lead to outbreaks? The development of disease following *C. burnetii* infection is – as in many other infections - influenced by so-called determinants of disease or risk factors. The presence of risk factors increases the probability of high levels of bacterial excretion, environmental contamination, and (zoonotic) spread of infection, development of clinical disease etc.

What are the risk factors for the development of clinical disease (Q fever) in animals? In ruminants, most infections by *C. burnetii* are asymptomatic, and the main clinical

manifestation is abortion. Consequently, two of the most obvious risk factors are being female and being pregnant [2, 3]. Clinical manifestations such as abortions may be sporadic in herds where few breeding females are present, whereas outbreaks may result in farms where many pregnant females are present, as is the case of intensive dairy sheep and goat farms, especially when reproduction is synchronized [10, 53, 56, 57]. Intensification of animal husbandry systems is thus considered an important risk factor for Q fever outbreaks [10, 20, 58].

In humans, clinical signs are different; they may be unspecific and quite variable. Abortions may occur, but they are not a main feature. Risk factors for the development of human disease are different from those of sheep and goats [1, 9]. For example, risk factors for the development of chronic Q fever, which may develop after primary acute infection (whether symptomatic or not), are pre-existing cardio-vascular conditions [2, 59]. Two important risk factors for the occurrence of Q fever outbreaks in humans are close proximity (< 5km) of humans to infected small ruminant farms, and intensive management systems of sheep/goat farms [3, 10, 52, 58, 60, 61]. Under certain circumstances, occupational exposure may play a role as a risk factor for *C. burnetii* infection and development of Q fever [4, 10, 62, 63]. Under others, such as outbreaks due to windborne spread, occupational exposure may play a minor role [3, 10, 58, 64].

NOTIFICATION, CASE DEFINITIONS AND SURVEILLANCE SYSTEMS

Public health surveillance has been defined by the World Health Organization (WHO) as “the continuous, systematic collection, analysis and interpretation of health-related data needed for the planning, implementation, and evaluation of public health practice” (see www.who.org). The objectives of surveillance systems include serving as an early warning system for impending public health emergencies; documenting the impact of an intervention or tracking progress towards specified goals; and monitoring and clarifying the epidemiology of health problems, to allow setting of priorities and to inform public health policy and strategies (also see www.who.org).

Notification

Q fever is a notifiable disease in many countries. Notifiable or reportable diseases have a legal framework by which they should be reported to official health authorities. Notification may be due at national, regional and/or international level [4, 18, 65–68]. Importantly, despite recommendations of notification at international level, national legal frameworks vary and notification is not compulsory in all countries [21]. For example, within 24 EU member states, Q fever is reportable in humans and animals in 17 and 15 member states, respectively [19]. The reasons for these discrepancies in reporting among countries may be at least two-fold.

On one hand, the relative importance of Q fever as compared to other health-related conditions varies with time and among countries [3, 37]. For example, in Kenya, Q fever is currently neither a notifiable disease, nor is it on the list of zoonotic disease of priority, as

there are other conditions with higher impact on animal and public health [37]. In the Netherlands, Q fever is notifiable since 1978, and until 2007 on average 17 cases were notified per year [49, 69]. The relative importance of Q fever increased in the Netherlands during the 2007-2010 outbreaks, when it jumped from a sporadic occurrence to an epidemic (outbreak) with an important public health impact on urban resident populations.

The second major reason for discrepancies in reporting Q fever can be related to difficulties in diagnosing the condition and on setting case definitions. The majority of infections with *C. burnetii* in humans and animals either run an asymptomatic course or are characterized by transient mild and nonspecific signs. These infections are generally (dis-) missed, especially in situations of low endemicity, when awareness regarding Q fever among medical and veterinary practitioners is low [3, 19]. On the other hand, it may be desirable to have monitoring activities in place at all times to allow early detection of outbreaks and rapid implementation of control measures to minimize public and animal health impact.

Case Definitions

Reporting systems require case definitions. A case definition states “when the sample is considered to be positive for the zoonotic agent or when the person, animal, herd or flock is considered to be infected with the zoonotic agent” [19]. Case definitions vary according to the objective of the study, so case definitions for seroepidemiological studies may differ from those for clinical diagnosis or from those of monitoring and surveillance purposes [4]. Importantly, mild cases may remain undetected if the patient does not seek medical attention, as only then and depending on medical awareness, it may be referred for laboratory confirmation [4, 7, 8, 70]. Underreporting is a very important feature of Q fever. During the large Q fever outbreak in the Netherlands, it was estimated that approximately 9 of every 10 infections were not notified [59].

Regarding human Q fever, case definitions for reporting purposes have been laid out, for example, by the European Commission to facilitate uniform reporting by member states [21]. Accordingly, Q fever (*C. burnetii*) diagnosis is based on clinical, laboratory and epidemiological criteria. At least one of the following three clinical symptoms: fever, pneumonia and/or hepatitis must be present. Additionally, at least one of the following laboratory criteria must be met: isolation of *C. burnetii* or detection of its nucleic acid from a clinical specimen, or a specific antibody response (IgG or IgM phase II). Finally, at least one of two epidemiological links must be present: exposure to a common source or animal to human transmission. Based upon these criteria, cases of Q fever in humans may be classified as “probable” if clinical and epidemiological criteria are fulfilled, or as “confirmed” if clinical and laboratory criteria are fulfilled. One potential drawback of these case definitions is that they mostly focus on acute Q fever. In the aftermath of major Q fever outbreaks, the necessity of early detection of chronic Q fever cases for treatment purposes increases [9, 59, 71]. The lack of precedence of large Q fever outbreaks in the past partly explains the focus of some notification systems on acute Q fever. In response to the large Q fever outbreak in the Netherlands new follow-up strategies of early detection for chronic Q fever in general populations were developed [7, 9, 71]. The distinction between acute and chronic Q fever is made in the criteria for surveillance purposes by the Centre of Disease Control, where cases

are defined as “confirmed” and “probable” based on clinical evidence as well as laboratory “confirmed” and laboratory “supportive” criteria [4].

For the purpose of diagnosis of human Q fever in a clinical context, case definitions are nearly always specified for acute and chronic manifestations. For example, acute Q fever may be suspected based on clinical signs such as fever, muscle pain, headache, pneumonia and other symptoms, especially if epidemiological links exist [1, 70]. Only once suspected, laboratory confirmation can be carried out [12, 56, 64, 71]. Chronic Q fever cases may be detected by screening high risk group patients, e.g., those with pre-existing cardiovascular conditions [9, 59, 71].

Regarding animal health, Q fever is listed as notifiable by the World Animal Health Organization [68]. Recommended diagnostic procedures and case definitions are laid out in the Manual of diagnostic tests and vaccines for terrestrial animals [5]. Similar as for humans, the diagnosis of Q fever in animals is based upon a combination of serology and PCR assays. But, although identification of *C. burnetii* from an individual animal could confirm diagnosis (similar as for humans), as a general principle, diagnostic test results should be interpreted at herd/flock level, together with its clinical history [5]. A positive Q fever case in animals is thus defined by the OIE as a herd or flock with clinical signs (abortion and/or stillbirth) for which the presence of the agent has been confirmed [2, 5, 19]. For monitoring and reporting purposes of Q fever in animals in EU member states, a Q fever case definition was proposed as a herd/flock with clinical pattern of coxiellosis (abortion and/or stillbirth), confirmation of the agents` presence and positive serology [19]. A distinction is made between “probable” cases where clinical signs (abortion and/or stillbirth) and positive serology was observed, and “confirmed” cases, where the presence of the agent has to be demonstrated.

Surveillance Systems

Surveillance and monitoring has been described as the “key defence against emerging pathogens,” often required to be “integrated across human, domestic animal and wildlife populations” [24, 72]. This could be illustrated by the 2007-2010 epidemic of Q fever in the Netherlands, whose magnitude and impact at animal and human health level could be estimated through monitoring and surveillance systems [49]. Monitoring can be defined as an intermittent performance and analysis of routine measurements and observations, aiming to detect changes in the environment or health status of a population [73], or as a system of collecting, analysing and disseminating data on the occurrence of zoonoses, zoonotic agents and antimicrobial resistance (Directive 2003/99/EC) [19]. Surveillance is the systematic ongoing collection, collation, and analysis of information related to animal health and the timely dissemination of information so that action can be taken [73]. Both, monitoring and surveillance are similar in the continuous observation of health related parameters, but only in surveillance systems, active control measures are taken when positive cases are detected [19, 73]. Because the distinction between monitoring and surveillance can be difficult, the single term monitoring and surveillance system (MOSS) has been proposed [24, 72].

As a consequence of the large Q fever outbreak in the Netherlands, harmonised schemes for the monitoring and reporting of Q fever in animals in the European Union were developed [19]. As Q fever outbreaks in humans are most frequently associated with *C. burnetii*

infection in domestic ruminants, passive and active monitoring systems were described which focus on domestic cattle, sheep and goats. Passive monitoring schemes aim to detect clinically affected herds/flocks of domestic ruminants by encouraging the inclusion of Q fever in differential diagnostic testing in all herds/flocks with abortions. Active monitoring, on the other hand, can be applied when the aim is to estimate the prevalence of *C. burnetii* infections in animal populations, e.g., when disease frequency in humans or animals is suspected to be high. Generally, large sample sizes are required for active monitoring, which turns it labour- and cost-intensive [19].

Q fever outbreak investigations represent excellent examples of multidisciplinary teamwork and practical application of the “One Health” concept [23, 45, 64, 74]. Similar to other recent major outbreaks of zoonoses, such as avian influenza, they illustrate the complexity and high scientific level of outbreak investigation nowadays, using methods such as molecular epidemiology [75], spatial modelling [46, 51, 74], vaccine effectiveness modelling [76] and atmospheric dispersion modelling [23].

IMPACT ON PUBLIC HEALTH

Public health is concerned with protecting the health of populations, and can be defined as “the science of protecting and improving the health of families and communities through promotion of healthy lifestyles, research for disease and injury prevention and detection and control of infectious diseases” (see www.cdcfoundation.org/). Veterinary public health is an essential part of public health linking the various disciplines of the epidemiological triad human-animal-environment. It can be defined as “the sum of all contributions to the physical, mental and social well-being of humans through an understanding and application of veterinary science” [77].

The estimation of the impact or burden of Q fever on public health can be a challenge. As mentioned above, unspecific clinical pictures and variability in disease awareness may lead to considerable underreporting. As opposed to mild *C. burnetii* infections or the occurrence of sporadic Q fever, major (relevant) public health impacts are usually related to outbreaks [19, 78]. For example, the large Q fever epidemic in the Netherlands resulted in a serious burden of disease, which can be described qualitatively by the hospitalisation of acute cases and, in the longer term, by the intense medical treatment and eventual premature death of chronic cases [9, 20, 79]. The impact on public health of Q fever has been measured by instruments such as the Nijmegen Clinical Screening Instrument (NCSI) or Short Form 36 (SF-36) [80–82]. These instruments are particularly useful for assessing the long term or chronic consequences of Q fever infections such as severe chronic fatigue [79, 82–84].

Quantitative assessments of the impact of diseases on animal and public health can also be made by different metrics. Economic impact studies assess lost labour productivity due to human illness or reduced tourism to affected areas, or, in the case of animal diseases, the reduced productivity and consequent reduced food production for human consumption [28]. In a recent economic impact assessment of the Q fever outbreak in the Netherlands, the biggest losses were observed in the public (human health) sector, with an estimated 222 Million Euro [50]. Interestingly, income losses due to chronic fatigue syndrome and chronic Q fever were considered substantial, as they accumulated over time, whereas treatment costs

accounted for less than 2% of the total human health costs. The second highest cost, of approximately 85 Million Euro, was related to disease control in the agricultural sector, whereas production losses on infected farms were considered relatively minor [50].

The impact and ranking of different diseases in terms of public health is commonly assessed using disability-adjusted life years (DALY). One DALY can be seen as one year of “healthy” life lost due to a specific disease (see www.who.int). For example, for the large Q fever outbreak in the Netherlands, the burden for human health was estimated to be 2,462 DALY’s, with chronic fatigue syndrome as the most prominent contribution [50]. Linking this estimate with the economic evaluation, the total intervention cost in agriculture was estimated as 35,000 Euro per DALY (85 Million Euro/2462 DALY) [50]. The use of DALYs further allows the comparison of different diseases. For example, for the year 2009 in the Netherlands, seasonal influenza by A(H1N1)pdm09 was estimated to cause approximately four times more DALYs than Q fever, but Q fever was shown to be 8 to 28 times more severe than influenza, because of the long-term sequelae of Q fever, whereas influenza’s burden was largely due to mortality [85].

CONCLUSION

Infections by *C. burnetii* and Q fever are very complex in terms of biology, epidemiology, diagnosis and control. In this chapter, a brief overview on the disease was given and relevant epidemiological terminology was defined and illustrated within the context of Q fever/coxiellosis. Transmission cycles between different hosts systems, the importance of distinguishing between infection and disease as well as the importance of case definitions for monitoring and surveillance systems were described. The impact of Q fever on public health may very quickly change from very low in sporadic single cases to very high in the case of major outbreaks. This chapter serves as an aid for the understanding for the remaining chapters.

Chapter 543

PHARMACOGENOMICS, REGULATORY AFFAIRS AND PUBLIC HEALTH

Diadelis Ramirez Figueredo, PhD*

National Centre for Quality Control of Drugs, Cuba

ABSTRACT

The science of pharmacogenomics has advanced significantly in the last five years. The Pharmacogenomics helps identify interindividual variabilities in drug response (both toxicity and effectiveness). This information will make it possible to individualize therapy with the intent of maximizing effectiveness and minimizing risk. The objective of this chapter is to present an overview about the international regulations about this topic and to present briefly the introduction of this science in Cuba. It was done a revision in the international literature about the existing regulations, guidance, concept paper, etc. The chapter illustrates the general requirements for regulation, e.g., reception, codification and sample storage, biomarkers, ethical consideration as well as it is explained the relation of this discipline with pharmacokinetics studies, bioequivalence trials and pharmacovigilance systems. Cuban guidance will be introduced which is focused to pharmacogenetic studies during the clinical phases of drug development. Pharmacogenetic has several advantages in order to get rational use of drugs but still there are many challenges which will be shown in this work. The hope for the future is that through personalized medicine, doctors and patients will be able to make better-informed choices about treatment. This treatment will avoid the adverse drug reaction to the medication and will improve the diagnosis diseases as well as the prevention and treatment of diseases.

Keywords: pharmacogenetics, pharmacogenomics, pharmacovigilance, regulatory, public health

INTRODUCTION

Pharmacogenetics, one of the cornerstones of personalized medicine, has the potential to change the way in which health care is offered by stratifying patients into various pretreatment categories, such as likely responders, likely non-responders or likely to experience adverse drug reactions. In order to advance drug development and regulatory science, regulatory agencies globally have promulgated guidelines on pharmacogenetics for nearly a decade (Evans, 2003).

Pharmacogenomics helps in identifying inter-individual variability in drug response (both toxicity and effectiveness). This information will make it possible to individualize therapy with the intent of maximizing effectiveness and minimizing risk beside that, pharmacogenomics allows optimize pharmacovigilance by identifying risk of adverse reactions and to improve the design of clinical trials by stratifying group population. Thus, it is important to regulate this subject in order to minimize the adverse drug reactions, make decisions based on risk benefit criteria, and allow the rational use of drugs based on other criteria and to avoid the discrimination of people (Gibbsburg & Willard, 2009).

The main mission of any regulatory agency is to control the quality, safety and efficacy of drugs. The main regulatory agencies around the world: Food and Drug Administration (FDA) from United States of America, Health Canada (Canada), European Medicines Agency (EMA) from Europe and Pharmaceuticals and Medical Devices Agency (PMDA) from Japan have issued guidance's about pharmacogenomics as well as the International Conference on Harmonization (ICH) which is integrated by FDA, EMA, PMDA and Pharmaceutical companies.

There are different regulatory dispositions related with pharmacogenomic studies; for example: concept paper, reflection paper, drafts, position paper, which explains how to implement the regulations and guidance about pharmacogenomic assays (FDA, 2016).

EMA is the regulatory agency with more regulations about this topic, followed by FDA and International Conference of Harmonization (ICH). These documents explain about the samples reception, the codification, the use of biomarkers. Recently, EMA published a new guide in relation with good practices for pharmacogenomic moreover there are guides which include the importance of Pharmacogenomic in the prescription as well as the drug rescue from the market and pharmacogenetic methodologies in pharmacokinetics studies, etc. On the other side, World Health Organization, in the technical report series, appears as potential risk the declaration of genetic polymorphism for its importance in the drug metabolized by polymorphic enzymes e.g. Cytochrome P-450 (CYP) 3A4 metabolize Indinavir and nelfinavir and promethazine is metabolized by CYP 2D6 (WHO, 2006).

Each regulatory agency has settled their guides according to the rational use of drug for their population, the safety and efficacy of the drugs and taking into account the context of every country for the further implementation.

In general the guidance's published are formed by the following chapters (EMA, 2006):

- Introduction
- Background
- Objectives and Scope

- Terms and Definitions
- Regulatory Requirements

Introduction: In this chapter it is explained a general summary of the regulatory disposition.

Background: Refers about the previous report about the topic of the guidance.

Objectives and Scope: Specify the aims of the regulatory disposition, and its scope should indicate whether the guideline concern a selected area of medicinal product development where limited experience is available and knowledge is fast evolving requiring the need for easy updates and flexibility.

Concerning to the regulatory requirements is mentioned the requirements recommended or demanded related with the codification of samples, the obligation in the use of biomarkers, ethical aspects, etc.

MAIN ITEMS IN THE GUIDELINES

Terms and Definitions

The uses of terms in this subject have been harmonized and these have been accepted by the international scientific community (Regulatory, academics, ethical committee, and health professionals).

Actually the terms pharmacogenomic and pharmacogenetics are frequently used interchangeably. The achievement of widely accepted working definitions of the two would be a useful first approach to applying pharmacogenetics and pharmacogenomics in clinical trials. It is important to single out pharmacogenetics and pharmacogenomics from the wider field of genetic testing as the latter encompasses different level of concerns especially in terms of sensitivity of sample handling, data and trial results management (ICH, 2016).

Pharmacogenetics: is the study of interindividual variations in DNA sequence related to drug response.

Pharmacogenomics: is the study of the variability of the expression of individual genes relevant to disease susceptibility as well as drug response at cellular, tissue, individual or population level. The term is broadly applicable to drug design discovery, and clinical development.

Other terms are also identified like, Mutation, Alleles, Single nucleotide polymorphism, Genomic Biomarker, Gene, Genotype, Phenotype, Locus (EMA, 2016).

MANAGEMENT AND STORAGE SAMPLES

The sample identification is very important for getting traceability of the results. According the guidelines published related with pharmacogenomic studies the samples and data can be identified in 4 general categories (Ricci et al., 2011).

- 1) Identified data: The samples are identified with personal identifiers such as (name, identification numbers, like social security or national insurance number), the right identification offers privacy protection similar to general healthcare confidentiality in everyday medical practice.
- 2) Coded Data and Samples. The data and coded samples are labeled at least with a unique code and do not carry any personal identifiers. These samples can have a unique or second label, the second code offers additional confidentiality, and second code is linked to the first code by a key. It is possible to trace the data or samples back to the individual by the use of both coding keys.
- 3) Anonymised Data and Samples: Anonymous data and samples are initially single or double coded but then the link between the subject's identifiers and the unique code (s) are subsequently deleted. Once the link has been deleted it is no longer possible to trace the data and samples back to the individual through the coding key (s). Anonymisation is intended to prevent subject re-identification.
- 4) Anonymous Data and Samples. Anonymous data and samples are never labelled with personal identifiers and therefore there is no potential to trace back genomic data and samples to an individual subject.

On the other side, the suitable storage is a key aspect for sample preservation, at the same time to the period of time for protecting the sample is very important, which can take several years. The biological samples could have variable quantities of nucleases in certain conditions, for this reason is important that samples have acceptable integrity in the storage conditions selected which should be checked and validated. All these process, reception codification and storage should fulfillment of good pharmacogenomic and clinical practices (EMA, 2016).

USE OF BIOMARKERS

Significant pharmacogenomic research has focused on understanding the molecular mechanism underlying certain adverse reactions and on recognizing biomarkers (BM)s that identify individuals at risk.

A genomic biomarker is a measurable DNA and/or RNA characteristic that is an indicator of normal biologic process, pathogenic processes, and/or response to therapeutic or other interventions (EMA, 2016).

A genomic biomarker could, for example, be a measurement of:

The expression of a gene

The function of a gene

The regulation of a gene.

There are 2 main types of BMs.

- 1) Predictive BMs: Are those that provide clues towards response (safety or efficacy or metabolic) to a particular therapeutic intervention, especially drug therapy. Evaluation of clinical utility of such predictive markers is facilitated by pivotal trials

conducted in defined patient populations, selected and grouped based on the marker (s).

- 2) Prognostic BMs: Those that indicate disease prognosis, that may not have an intrinsic relation to specific intervention, either drug therapy or otherwise. Thus prognostic BM may or may not provide the basis for a clinical decision or influence the decision algorithm for treatment or intervention. However, studies evaluating prognostic GBMs may provide a scientific background of the natural history of the disease, facilitate development of additional other biomarkers (genomic or non-genomic) and contribute to drug development indirectly.

Another important aspect is the critical parameters for the choice Biomarker assay.

The intended use of the BMs should be thought before development and validation of the chosen assay.

CRITICAL PARAMETERS FOR THE CHOICE BIOMARKER ASSAY (EMA, 2016)

- 1) Assay-specific considerations. These include, known attributes of analytical sensitivity, diagnostic sensitivity, specificity, accuracy, repeatability, reproducibility, linear range of quantitative assays including control of known relevant interference, and limits of detection.
- 2) Preanalytical factors: General principles of specimen acquisition regarding BMs, sample type, patient or subject selection criteria, conditions and preparation for sampling, sample handling, e.g., storage conditions, extraction procedure.
- 3) Analytical factors: Assays protocol, assay platform including amplification efficiency, linearity, precision, dynamic range as well as limit of detection, calibrators and software and algorithms used for the interpretation of results, performance variables.
- 4) Post analytical factors: Data handling and processing, relevant published data, meta data and standards available, comparative performance with relevant standard if available or state of the art test.
- 5) Validation steps in the development of an assay for a pharmacogenomic biomarkers: Assay performance evaluation: Validation of analytical performance, validation of in vivo clinical performance as relevant for context and intended uses (i.e sensitivity and specificity in detecting clinically relevant response), further plans in post market surveillance to confirm clinical utility.

Therefore, a biomarker should be qualified as early as possible for promoting its use in drug development when reasonable evidence for a particular context of use is available.

Another important point to consider is that a biomarker should be qualified internationally rather than by a single regulatory agency because most drugs are currently developed globally, and conducting a MRCT has become a standard strategy for drug development. For global drug developments, an internationally qualified biomarker is

necessary so that the data can be submitted to multiple regulatory agencies for a regulatory review and decision-making (EMA, 2016).

A big challenge is ‘biomarker qualification’. A PGx biomarker to be used in drug developments should be qualified and accepted by a regulatory agency because use of an unqualified and unacceptable biomarker may result in misinterpretation of the acquired data due to false signals (false-positive or -negative signal) and, therefore, may not be used in regulatory decision-making. Biomarker qualification by a regulatory agency is an important process to qualify the objective and context of use of the biomarker before it can be widely used in drug development. To confirm the acceptability of the biomarker, each agency – PMDA, the FDA and the EMA – has established a biomarker qualification process. Thus, in many cases the identified biomarkers are used for more than one drug and consequently the same biomarker can be used for different indications, for example, Glivec for several types of leukemia but also for stromal tumours (Otsubo et al., 2013). Figure 1 shows some of the differences in required pharmacogenetics testing between EMA and FDA. The vast majority of drugs/78%) have similar label requirements for diagnostic testing in both geographies.

Figure 1. Drug required pharmacogenetic companion diagnostic testing.

Biomarkers open a new era for pharmaceutical companies concerning the Companion diagnostics for drugs mainly for cancer treatment in order to guarantee the safety and efficacy of the drugs and the reduction of the cost (Berryessa et al., 2013).

ETHICAL ISSUES

This is a big challenge in this subject, particularly as science and technology continue to advance very rapidly. Whole genome sequencing, for example, is poised to eliminate the need for individual genetic tests, thus raising ethical concerns about the creation of genetic information which individuals may or may not want to know and which may or may not remain privately secured. Ethical Committee has a great responsibility, should approve the pharmacogenomic studies taking into account, Balancing risk-benefit, Ethical responsibilities

of all the participants in the study, The patients need all necessary information to make the own decision. All anticipatable information of expected benefits or expected harms. Concern of individual participants regarding anonymity, privacy and confidentiality should be respected and should be addressed in a research agreement the discrimination should not be allowed and the protocol should always refer the alternative treatment in case the patient according the result cannot take the drug assayed (Issa et al., 2002).

Another important point is the Investigation in biological samples with genetic material because (Berryessa et al., 2013):

- 1) Genetic material is unique for each person and does not change along the time. It means that patient will be potentially identified.
- 2) Because DNA is stable. Would be capable of multiple researches. Many of them are not in related to the goals for which they were gotten.
- 3) The samples that will be taken for pharmacogenomic assays could be useful in order to know the diseases which the subject does not want to know.
- 4) Because genetic material is common for parents and brothers, the finding could have implications for subject relatives what shows as results individual ethical problems.

Pharmacogenetics allows researchers to conduct gene profiling to answer questions about patient responses to medicines, which results in the design of safer and more effective medicines. The science and its applications are real today and will be increasingly utilized in coming years. While it is extremely unlikely that individuals will be excluded from health insurance because of their response (or lack) to a particular drug, or that they will be subject to employment exclusions (in hiring, promoting or job responsibilities), ethical issues are central to policy debate about the appropriate use of pharmacogenetic testing and its related benefits (Berryessa et al., 2013).

The European regulatory strategy adopted in recent years to raise awareness via informing health-care professionals by adding pharmacogenomic information in drug label is evolving and is now increasingly providing practical guidance on why, when and how to obtain pharmacogenomic individual patient's data to facilitate pharmacogenomics (PGx)-guided drug treatment.

To further promote the scientifically sound integration of PGx in product development and consequently the product label and patient treatment, the EMA sets recommendations and requirements for the investigation and incorporation of PGx in drug development and surveillance/ pharmacovigilance.

In addition, the Agency has elaborated guidance on the importance of identification and validation of genomic biomarkers 10–13 and established a number of activities (Ehrman et al., 2015).

Drug labels form an intrinsic and integral part of the marketing authorization and are intended to guide patient treatment.

The Summary product characteristics (SmPC) is the basis of information for health-care professionals on how to use the medicinal product safely and effectively and the SmPC thus sets out key elements of drug benefits and risks relevant to the clinical use of the product defined during the medicine regulatory assessment process. Regulatory recommendations on how pharmacogenomic information shall be presented in the EU labels have been published (EC, 2016).

The description and place of pharmacogenomic information in the label (SmPC section) has also an important impact on reimbursement not only for the drug but also for the related companion diagnostic test used and potentially liability implications for the treating health-care professionals.

Almost 15% of EMA-evaluated medicines contain pharmacogenomic information in their label that directly impacts patient treatment. These sections include Therapeutic indications, Posology and method of administration and Contraindications etc. (EC, 2016).

In Table 1 it is shown, the information in each chapter.

Table 1. Types of PGx information for labeling

Section of Label.	Pharmacogenomic (PG) information.
Therapeutic indications	If the product's indication depends on a particular genotype or the expression of a gene or a particular phenotype, then this should be stated in the indication.
Dosage and administration.	Where necessary, dosage adjustments in patients with a particular genotype should be stated (with cross-reference to other relevant sections for further detail as appropriate).
Contraindications.	Linked to a particular genotype.
Special warning and precautions	Subjects or patients with a specific genotype or phenotype might either not respond to the treatment or be at risk of a pronounced pharmacodynamic effect or adverse reaction. These may arise because of non-functioning enzyme alleles, alternative metabolic pathways (governed by specific alleles) or transporter deficiencies. Such situations should be clearly described if known.
Drug Interactions.	If interactions with other medicinal products depend on polymorphisms of metabolizing enzymes or certain genotypes, then this should be stated.
Undesirable effects.	This section may include information on any clinically relevant differences specifically observed in patients with a specific genotype.
Overdose.	If applicable, counteractive measures based on genetic factors should be described.
Pharmacodynamic properties.	Any relevant pharmacogenetics information from clinical studies may be mentioned here. This should include any data showing a difference in benefit or risk depending on a particular genotype or phenotype.
Pharmacokinetic properties.	Variations with respect to polymorphic metabolism should be described, if clinically relevant, in quantitative terms.

More than 200 drug labels in the US, corresponding to about 10% of drugs approved by the FDA, contain pharmacogenetics information, still a relatively small figure. But it shows that a significant number of relationships between genetic markers and pharmacokinetic or drug response phenotypes are potentially relevant. Both at Food and Drug Administration and

at European Medicines Agency (EMA) pharmacogenomic information in drug labels is increasingly present and consequently tailored drug therapy to patients' genetic make-up can lead to improved benefit-risk balance of drug treatment by optimization of the target population and by tailored choice of drug treatment and drug dosages resulting in improved drug efficacy including minimization of adverse drug reactions (ADRs) (Eichelbaum et al., 2006).

There are several differences in how the main agencies deal with critical issues in the application of pharmacogenetics to pharmacokinetics parameters and these are highlighted in Table 2.

Table 2. Summary of differences between the three regulatory guidelines on pharmacogenetics. (Malliepard et al., 2013)

Issue	Regulatory agency.		
	European Medicinal Agency.	Pharmaceutical and Medical Devices Agency, Japan.	US Food and Drug Administration.
Development phases covered in guideline or guidance.	Preclinical and clinical development (Phase I-IV, focusing on PK).	Clinical development (Phases I-IV).	Early clinical development (Phases I and II).
Banking of DNA samples.	Highly recommended.	Recommended.	Recommended.
Genomic testing	Required	Recommended	Recommended
In vitro cut-off values*	> 50%	None	None
In vitro cut-off values*	> 25%	None	None

*It is firm requirement only when in vitro (> 50%) or in vivo (> 25%) cut-off values are met. For when pharmacogenetics-related testing is required in pharmacokinetics studies.

Health Canada, the Canada Regulatory Agency, has adopted ICH guidance Definitions for Genomic Biomarkers, Pharmacogenomics, Genomic Data and Sample Coding Categories E-15. In general the regulatory agencies have exchanged through different meeting, working party about Pharmacogenomic. There is consensus among the regulatory authorities concerning this topic.

Current Status of Pharmacogenomics in Latin-American Countries

Several studies have been done with Latin-American population related with the study of the variability of pheno- and genotypes in Hispanics. Most of these studies have been carried out through Ibero American Network of Pharmacogenomic and Pharmacogenetic. Studies related with the polymorphism of CYP isoenzymes (CYP 2C9, 2C19, 2D6) and variability in the drugs response have been done with population from Costa Rica, Peru, Uruguay, Cuba, Argentina, Nicaragua, Ecuador, Chile, Colombia, México. One of the studies describes the frequency of the most relevant pharmacogenetic biomarkers and metabolic phenotypes in

Central American healthy volunteers and to determine its interethnic variability. Twenty-six original research articles on allelic, genotypes or metabolic phenotype frequencies were analyzed, in which a total number of 7611 Central American healthy volunteers were included (6118 were analyzed for genotype and 1799 for metabolic phenotype). No reports were available for population from Belize and Honduras. The CYP2D6*4 and *5 frequencies in Amerindian populations from Costa Rica have shown to be among the highest frequencies so far reported in the world. Furthermore, NAT2*5 and *6 presented high frequencies in admixed populations than in Amerindians, but, inversely, the NAT2*7 was more frequent in Amerindians compared to an admixed population. Likewise, different patterns of distribution have been shown in HLA-A*02, *03 and HLA-B*07 among Native populations from Latin America. Reports on Central American populations were also found for the CYP2C19, LDLR, CYP2E1, MDR1, G6PD, TP53, CYP1A2, CYP3A4 and CYP3A5 biomarkers, but no data were available for the other 91 pharmacogenetic biomarkers revised in Central American populations. Differences in the frequency of some pharmacogenetic biomarkers and metabolic phenotypes were found, showing interethnic variability within Central American and with other Latin American populations (Céspedes-Garro et al., 2014, Rodeiro et al., 2012).

The main implications for the implementation in Latin-American are: the population are very heterogeneous, so that there is great variability in the drug response, another important aspect is the access to the drugs for every people is not equal is limited, according to the economical support, for this reason, the persons could be discriminated for using specific drugs, it means that people need the medicines and they cannot get them. There is a fragmentation of health care system according the health insurance. Latin-American is a continent which imports drugs and posologies, the drugs are sold in these countries but they have not assayed in them, another barrier is related to the need for clear guidelines for the use of pharmacogenomics in clinical practice due to the cost of trials.

Some of the possible solutions are: to create global development programmes, in several countries rather use bridging studies, the vital need is the education of health professional and the community, particular attention for special populations, like children and geriatrics patients, other relevant aspect is access to the information, and trials for the populations of Latin American countries. Pharmacogenetics should be introduced with the focus on the benefit for the majority of the population (Quiñones et al., 2014; Llerena, 2015).

CONSIDERATIONS ABOUT CUBA

Cuba is a country with heterogeneous population, with a growing development of biological product, which are subject to pharmacogenomic studies, these products are mainly for cancer treatment, for this reason is very important the right response to the patients (25). On the other side there are some pharmacogenetic studies with Cuban population through Pharmacogenetic Iberoamerican Network. Some of them are: It was demonstrated on debrisoquine hydroxylation in a Cuban population, moreover, differences on the frequency of ultrarapid metabolizers. The frequency of poor and ultrarapids metabolizers between Cubans and Spaniards have been determined, these results could explain inter-individual and

interethnic differences on drug response such as side effects or the therapeutic failures among Cuban patients receiving treatment with CYP2D6 substrates (Gonzalez et al., 2007).

The role of CYP2D6 activity variation in a sample of Cuban women with regard to their risk of eating disorder symptoms was evaluated and the results showed that there is a relationship between individual at risk of bulimia symptoms and increased CYP2D6 hydroxylation capacity in healthy Cuban women which supported previous finding about the relationship between eating disorders and CYP2D6 active genes (Lledó et al., 2012).

Taking into account the previous resulted and development of Cuban biotechnology, The Cuban Regulatory Agency, has clinical regulatory framework, which involves 5 main guidance (CECMED, 2016).

- 1) Requirements for authorization and modification of clinical trials.
- 2) Good Clinical Practices in Cuba.
- 3) Requirements for notification and reports of serious and unexpected adverse events in the clinical trials.
- 4) Requirements for clinical trials phase I and II with local products under investigation destined to the Cancer and AIDS treatment.
- 5) Requirements for availability and bioequivalence studies.

Recently it has been elaborated a guidance for carrying out pharmacogenetic studies during the clinical phases of drug development, it is oriented to the Industry, and this guide is focused to give some recommendations about this assays for example the use and type of biomarkers, sample codification, ethical aspect, a proposal of consent informed is proposed. This guide is about to be approved.

OTHER IMPORTANT ASPECTS FOR PHARMACOGENOMIC REGULATIONS

Bioequivalence Studies

In bioequivalence studies, intra-individual variability (CV_w) is critical in determining sample size. In particular, highly variable drugs may require enrolment of a greater number of subjects. We hypothesize that a strategy to reduce pharmacokinetic CV_w and hence sample size and costs would be to include subjects with decreased metabolic enzyme capacity for the drug under study. Regulatory agencies indicate that bioequivalence studies must be conducted in homogeneous but representative samples of the general population, ensuring external validity of the results. The pharmacogenomic assays are very useful for bioequivalence studies so that if the metabolic enzymatic capacity of the subjects is known for the assayed drug, this is clearly essential for the analysis of drug safety and efficacy to ensure that the results can be generalized to the whole population. However, as the main purpose of bioequivalence studies is to assess differences among drug products' bioavailabilities, decreasing intra-individual variability might increase the accuracy of determinations of drug-related factors (González-Vacarezza et al., 2012).

Use of Pharmacogenomic Methodologies in the Pharmacovigilance Evaluation of Medicinal Products

Some genomic biomarkers may predict drug exposure or the risk status of a patient related to adverse drug reactions (ADR). Genomic factors may play a role in the pathogenesis of both predictable and unpredictable ADRs as well as in clinical progression of diseases and rescue drug withdrawn from the market. Currently, there is limited information on the utilization of a genomic biomarker during follow up (post marketing) or on the effect of labeling with genomic information.

It is proposed guidelines to further discuss the following aspects (EMA, 2016).

- 1) Systematic consideration of pharmacogenomic effects and the implications of genomic biomarker use in the target population in the risk management plan (RMP) for:
 - a. Suspected/identified lack of efficacy/effectiveness of a relevant medicinal product related to the use of a genomic biomarker.
 - b. Safety concerns of a relevant medicinal product related to the use of a genomics biomarker.
- 2) Early consideration of when post authorization genomic data may need to be monitored or collected to confirm appropriate dose and co-medication, as well as to provide information or advice based on identified genomic biomarkers.
- 3) Collection and storage of genomic material (e.g., DNA or other) during clinical trials and upon the occurrence of serious ADR, lack effectiveness post authorization or unexpected worsening of the condition.
- 4) Methodologies for post authorization safety studies and post authorization efficacy/effectiveness studies regarding pharmacogenomic and biomarkers related issues (for adverse drug reaction and for lack of effectiveness) in the post marketing setting.
- 5) Consideration of the level and type of evidence for identification of signals, and how to report to the competent authorities (e.g., in RMP updates, periodic safety update reports published studies etc).
- 6) Consideration of risk minimization measures depending upon the importance of the possible clinical implications.
- 7) Labelling issues
 - a. What pharmacogenomic information to include in the product information (PI) and in which sections.
 - b. Assessing the impact of information in the product information on the use of the medicinal products.
 - c. Consideration of monitoring the effectiveness of genomic biomarker use in a clinical setting if there are requirements or recommendations in the product information on the use of genomic biomarkers.

The document is expected to provide for both industry and Regulatory Authorities regarding the application of pharmacogenomic methodologies in the pharmacovigilance evaluation of medicinal products and to support the development of methodologies for monitoring of the effectiveness of genetic biomarker use in the clinical setting.

Use of Pharmacogenetic Methodologies in the Pharmacokinetics Evaluation of Medicinal Products

The pharmacokinetics of many medicinal products is prone to interindividual variability, which is caused by several factors such as gender, age, weight, impaired renal and hepatic function and genetics. For drugs where pharmacogenetics is important, for pharmacokinetic variability there are guidelines which recommend that pharmacogenetics should be implemented in the drug development process. Genetic variants can influence a drug pharmacodynamics but also the absorption, distribution, metabolism and excretion of a drug. Furthermore, pharmacogenetics may also influence the formation, distribution and elimination of metabolites and this should be remembered if there are metabolites that may affect the efficacy and/or safety of the administered drug. Genotypes leading to absent decreased or increased enzyme or transport protein activity affecting the pharmacokinetics of the investigated drug and major pharmacologically active metabolites should be considered. Studies of the effect of pharmacogenetics on the pharmacokinetics of an active substance (parent and/or active metabolite) and its implication for efficacy and safety during development are generally required when the magnitude of the interindividual variation in drug exposure is so high as to likely influence the safety and/or efficacy of the drug in genetically variable populations. Factors that identify such a situation are (EMA, 2016):

- a. In vitro and/or in vivo studies indicate that known functionally polymorphic enzyme or transporter is likely to represent an important pathway in the metabolism or distribution of the drug or
- b. In vitro and/or in vivo studies that known functionally polymorphic enzyme or transporter is likely to represent an important pathway in the formation, elimination or distribution of a pharmacologically active or toxic metabolite, or
- c. In vivo studies indicate substantial interindividual differences in the pharmacokinetics of the drug likely to influence the efficacy or safety of the drug in the variable subpopulation, which cannot be explained by other intrinsic or extrinsic factor:

Studies on the effect of pharmacogenetics on the pharmacokinetics of an active substance and its implications for efficacy and safety are generally recommended during development if:

- a. Available in vitro data indicate that a human polymorphic enzyme or transporter contributes to the pharmacokinetics of the active substances but the quantitative role may be low based on the in vitro data or,
- b. There is high interindividual pharmacokinetic variability or there are pharmacokinetics outliers with higher or lower exposure to the active substance which cannot attributed to other known intrinsic or extrinsic factors, but which possibly can give rise to clinical efficacy and safety concerns based on the existing knowledge, or
- c. Major differences in pharmacokinetics are observed in different ethnic groups, which cannot be attributed to other known intrinsic or extrinsic factors.

Other recommendations have been made on how to implement pharmacogenetics during the different phases of clinical development, starting with in vitro studies conducted before investigation of the medicinal product in man. As a general rule, genotyping of the population included in a drug-drug interaction study for a relevant gene is recommended when pharmacogenetics are expected to affect the pharmacokinetics of any of the drugs included in the study. Because interactions might differ in subgroups of different pharmacogenetic genotypes, genotyping for the enzymes and transporters involved in the interaction should be carried out when appropriate (van Schie et al., 2011)).

CONCLUSION

Consideration of pharmacogenetics is also important in global drug development. Pharmacogenetic analysis in multi-regional clinical trials (MRCTs) will provide useful scientific data for understanding similarities and differences in drug responses (efficacy and/or safety) among various ethnicities. Specifically, when large differences in pharmacokinetics (PK) parameters among different populations is observed, pharmacogenetic analyses are useful for the examination of the reason or reasons for the differences and to set an appropriate dose for each population in later clinical trials (such as an exploratory dose-finding study) (Warner et al., 2011).

Pharmacogenomics-guided drug development has been implemented in practice in the last decade, resulting in increased labeling of drugs with pharmacogenomic information. However, there are still many challenges remaining in utilizing this process.

Main Challenges

- Education for health professionals and the community.
- Lack of familiarity with pharmacogenomics data.
- Resistance to the routine use of pharmacogenomics in medical care.
- Legal assurance.
- Interaction of the parties involved (patients, health-care professionals, authorities, health insurance companies and scientists).

As it comes to clinical translation, PGx is faced with big hopes and high expectations by everybody involved: patients who demand effective treatment free of adverse effects; physicians in need of guidance for selecting the most appropriate drug and the right dose for the patient; health care providers who have to find ways to improve medical care while reducing cost at the same time; regulatory agencies who need proof of concept to issue guidelines and laws, and also drug developers who are in fear of losing their costly drug candidates due to unforeseen toxicity in late stages of development (34).

In short integration of pharmacogenomics in clinical practice needs training of healthcare professionals and citizens, moreover legal and regulatory guidelines and safeguards will be needed. The answers to the questions of which patient should receive which drug and dose will be not easy, but we believe that the approach offered by pharmacogenomics should be

incorporated into the decision-making process. A more rational use of expensive treatment drugs together with actions to minimize patient toxic events and its consequences, would dramatically reduce medical costs as an added benefit.

Chapter 544

THE OFFER OF ALTERNATIVE/COMPLEMENTARY THERAPIES IN THE BRAZILIAN PUBLIC HEALTH SYSTEM AND CONSIDERATIONS ABOUT THE LIMITS OF THE NEW AGE

Rodrigo Toniol*

Universidade de Campinas, Brasil

ABSTRACT

The author explores the public health system in Brazil and its relationship with the field of alternative and complementary therapies. In his article, he said that the recent availability of alternative therapies in Brazil's public health system is a result of the 971 Interministerial Order which, in 2006, established the National Policy of Integrative and Complementary Practices (PNPIC). Such policy aims at ensuring and promoting access, through the Unified Health System (SUS), to traditional Chinese medicine, homeopathy, phytotherapy, thermalism, and anthroposophical medicine. The announcement of the PNPIC created the opportunity for states and municipalities to elaborate their own policies and guidelines regarding the provision and use of Integrative and Complementary practices (ICPs) in the SUS.

In this chapter, whose focus is on the policies of ICPs, Toniol investigates the processes of legitimation and regulation of such therapeutic practices within SUS, as well as their implementation routines in health care units, clinics and public hospital in Rio Grande do Sul. The author begins by analyzing the invention of Integrative and Complementary Practices (ICPs). Invention of ICPs refers here equally to the production of bureaucratic state records that are specific to such policy, and to the daily work of therapists, physicians and managers who strive to turn alternative/complementary therapies into ICPs. With this in mind, Toniol concludes that the ICPs policies, in addition to legitimizing the availability of alternative/complementary therapies within SUS, likewise create the regulatory tools for carrying out such practices. In the second part, the author looks into the ties established between ICPs, spirituality and health. Here

* Corresponding Author's Email: rodrigo.toniol@gmail.com.

he explores both the normativity of these links by surveying documents produced by health care managing organizations, and the policy's practical implementation in clinics. Contending that the category of spirituality deserves attention on its own, Toniol demonstrate that the notion of "spirituality" has been mobilized agents and institutions involved in the provision of alternative/complementary therapies within SUS. The author indicates, lastly, that the provision of ICPs within SUS has become an official means of drawing attention to the spiritual dimension of health.

Keywords: alternative/complementary therapies, health system, Brazil

INTRODUCTION

Anthropological criticism customarily identifies substantial ties between so-called alternative therapies and the new age.¹ Two sets of parallel – although connected – arguments reinforce this understanding. The first is the affirmation that there is a historic relationship between the rise and popularization of some of these therapies and the new age movement. After all, it had been in the realm of the countercultural movements that therapeutic practices such as meditation, yoga and oriental healthcare modalities expanded in the West (see Kemp; Lewis 2007). The second is that beyond a historic connection, there was an ontological compatibility between new age principles and the form of understanding the relationship between health and disease that supports alternative therapies. I have already closely addressed the delineation of these characteristics in other texts (Toniol 2015a), here, I will merely indicate that alternative therapies constitute, according to a significant part of the literature, the privileged form of healthcare for subjects and groups identified with the new age. Moreover, the association made between the new age, health and alternative therapies, forms a type of tautological connection, in which the therapies themselves serve to establish the marks of what would be the new age and the new age is used to explain the phenomenon of alternative therapies.

The attention that social scientists of religion have given to delineating new age phenomenon have benefitted studies about alternative therapies, given that it considered them as objects pertinent to anthropological analysis. It is not by chance that the period of emergence of the investigations dedicated to the therapies coincides with the main moment of interest in the new age, which took place particularly during the 1990s and early 2000s. At the same time, the presumption of – or the insistent analytical emphasis on – the link between alternative therapies and the esotericism of the new age made it difficult for anthropologists to focus on processes that were progressively taking place in Brazil, and which to some degree were counter to the perspectives that conceived these practices as being deinstitutionalized, non-modern, counter-hegemonic, etc. I refer to processes that have been realized at least since the mid-1990s, such as the emergence of unions of holistic therapists, the rise of a political agenda in the national congress dedicated to regulating the profession, the teaching of alternative therapies in healthcare courses in public universities and, finally, support for the

¹ A first version of this article was published in Portuguese in number 16, volume 2, of the journal *Revista de Estudos da Religião*.

promotion and offer of these practices under the public federal Unified Health System (SUS).²

My purpose is not to deny the historic relevance of the association between the new age and alternative therapies. But I will affirm that it is important to not treat this relationship as an analytical *a priori*. Therefore, I insist on the need to question understandings that see a supposed tie with the new age to any modality of use and offer of alternative therapies. Despite the apparent triviality of this argument, its explicit enunciation is necessary, given that in the literature of the social sciences of religion there are few contributions that identify modes of existence of alternative therapies outside the empiric scope and analytical-conceptual language of the new age. The argument that I present in this text can be synthesized in the following idea: the indiscriminate use of the analytical focus of the new age does not illuminate, but makes invisible important processes and transformations in the field of alternative therapies. In this case, using a frequent concept from the field, what is at stake is recognizing that the new age as an analytical category, beyond being a mystic-esoteric nebula, as Françoise Champion suggested in an effort to affirm the porosity of the phenomenon (1993), may also have become a smoke screen for social scientists of religion (Tonio 2015b; 2016).

In the sections that follow I give visibility to other configurations and modes of existence of the so-called alternative therapies. I will emphasize the condition of alternative therapies as officialized and legitimated in the scientific-political field and supported by law. Based on these cases, I will present configurations of the use and offer of alternative therapies that shift the analytical rhetoric of the new age in at least three dimensions: a) in these configurations, the offer of alternative therapies is not aimed at a middle class, urban educated user and is not concentrated in the central neighborhoods of large cities. To the contrary, new agers here, at least in the Brazilian case, are users of Brazil's public healthcare system;³ b) for the public legitimation of these therapeutic practices, their experts mainly mobilize texts from the resolutions, laws and public policies promulgated by healthcare agencies (state and municipal secretariats of health and the World Health Organization), and rarely make reference to contact with a master or guru; c) the scientific-political legitimation of alternative therapies involves a necessary denial of proximity with the new age and, as a complement, the enactment of long-term institutional processes through which the World Health Organization (WHO) recognized the so-called traditional medicines, for example.

I insist that what is at stake here is not to deny the historic ties between alternative therapies and the new age phenomenon, but to ponder the uses of these ties as a justification for the use of the conceptual-analytical language of the new age to address any modality of realization of alternative therapies. In a more immediate plane, therefore, the sections that follow serve to differentiate a set of terms such as alternative/complementary therapies, traditional medicine, integrative and complementary practices and alternative and complementary medicine and indicate the existence of distinct configurations for the reality of each one of them. Moreover, an important argument will remain latent throughout this text: the variety of the phenomenon described as characteristic of the new age, allied to the

² The thesis by Fátima Tavares, *Alquimistas da cura*, is one of the exceptions in this field. Originally presented in 1998, this text conducts a seminal analysis about the beginning of the formation of holistic therapist unions in Rio de Janeiro and São Paulo (Tavares 2012).

³ The Unified Health System is the public healthcare system available throughout Brazil in a free and universal form, it is the world's largest public healthcare system.

insistent tendency of social scientists of religion to impute the category in their ethnographies, is what allows questioning if the systematic use of this analytical language has imprisoned the multiplicity of the realities observed in a fiction used to describe them.

The sections that follow synthesize part of the official path of legitimation and regulation of the offer and use of alternative therapies in Brazil, which has been my object of analysis for the past five years. The data presented result from this research and come mainly from participant observation in commissions dedicated to the issue in official entities that coordinate and plan Brazil's national and public SUS, from interviews conducted with public administrators and healthcare practitioners as well as official documents. I will focus on the terms used by the policies for integrative and complementary practices, which were capable of legitimizing the offer of alternative therapies in the SUS. I then associate the Brazilian process to the steps that have already been taken by the World Health Organization to recognize traditional medicine and complementary and alternative medicine as healthcare practices.

THE CONVERSION OF ALTERNATIVE/COMPLEMENTARY THERAPIES INTO INTEGRATIVE AND COMPLEMENTARY PRACTICES

On December 2013 the southern Brazilian state of Rio Grande do Sul approved the State Policy for Integrative and Complementary Practices (PEPIC/RS).⁴ In conformity with the text drafted by a commission of technicians and specialists in the field, the state secretariat of health published a decree that assured the implementation of the following practices in the state's healthcare network: floral therapies, integrative corporal practices, manual and manipulative therapies, community therapy and diet-therapy. In addition, the same document also recommended the insertion of meditation, chromotherapy, music-therapy, aromatherapy and geotherapy to care provided at health clinics and hospitals in the state. These therapeutic practices are combined with those that were already approved in 2006 when the National Policy for Integrative and Complementary Practices established the guidelines for implementation of phytotherapy, acupuncture, homeopathy, crenotherapy and anthroposophic medicine, in the entire network of the country's Unified Health System.⁵

Like Rio Grande do Sul, other states have also approved their own policies for integrative and complementary practices, and with this have added new practices to those already included in the national policy. This is the case of Minas Gerais, Santa Catarina, Rio Grande do Norte and Espírito Santo, to mention just a few examples. In the wake of enactment of the National Policy for Integrative and Complementary Practices, a series of municipal laws and decrees have been issued dedicated to these therapeutic practices. The municipal government of Santo Angelo in the interior of Rio Grande do Sul, for example, instituted, the municipal natural therapies program, in a decree. The main objective of the program is to implement, in

⁴ See Rio Grande do Sul 2014.

⁵ In 2017 the National Policy for Integrative and Complementary Practices was reformulated and also came to call for the offer of shantala, reiki, reflex-therapy, chiropractic, integrative community therapy, naturopathy, osteopathy, Yoga, circular dance, biodance, Ayurveda and art therapy.

the municipal health clinics, service based on practices such as: biotherapy, bioenergetics, iridology, hypnosis, alphatherapy, oligotherapy therapy, radiesthesia and others.⁶

The publication of the National Policy for Integrative and Complementary Practices in 2006 encouraged states and municipalities to produce their own policies and guidelines related to the offer and use of the integrative and complementary practices in the SUS. My interest is not in discussing the effectiveness of each one of these policies or to evaluate if they have had concrete repercussions on the routine of healthcare units in the country. My objectives are related to the specific terms that these policies for promotion of the integrative and complementary practices use to legitimate and regulate what they call integrative and complementary practices. Thus I begin with the understanding that, at the same time as the public policies dedicated to the integrative and complementary practices legitimate these therapies as part of the official healthcare service, they also inscribe them in a specific regime of classification and regulation. Using as a predominant reference the National Policy for Integrative and Complementary Practices, in the following sections I will problematize the terminology used by the policy that is, the categories mobilized to justify and frame the offer of these practices in SUS.

As a regulatory instrument, the National Policy for Integrative and Complementary Practices produces a series of demarcations. The most evident is the very broad category integrative and complementary practices. The term was created by members of a commission charged with developing that policy and competes with a long list of others, such as alternative, complementary, natural, and parallel therapies as well as romantic, complementary and alternative, non-hegemonic or non-formal medicines. If on one hand, all of these categories converge on some aspects of the practices that they designate, on the other, their multiplicity does not only raise a problem of a nominal order. They also indicate specific relations with the state and with its modalities of regulation that define how and who is authorized to treat, diagnose and cure. As Waleska Aureliano (2011, 168) affirms, the difficulty created by constructing broad classifications for these other medicines is related not only to the plurality of practices to which they refer, but above all, to the fact that they involve distinct modes of relation with the official spaces of healthcare. These, in turn, are based on the differentiated modes with which they historically construct and negotiate their legitimacy with the state.

Thus, I consider it necessary to reflect on how to denominate the so-called alternative therapies. The mode of designating these therapeutic practices is important for two main reasons: first because the use of certain broad categories immediately inscribe the practices analyzed in certain theoretical perspectives – this is the case of designating them as medical rationalities,⁷ for example. Second, because some of these terms are summarily rejected by part of their practitioners – for example, by acupuncturists who refuse the category alternative therapy because it establishes a relation of divergence with a principal therapy. For this reason, I opt here for a terminology that seeks not to make invisible this nominal permanent tension, by using the composite term alternative/complementary therapies. The solution is only partial, but serves to indicate the unstable and controversial character of the designation of these practices. In addition, by referring to the category as alternative/complementary therapies, I benefit from the possibility of indicating their difference in relation to the official

⁶ I am referring to lei n° 3.597, of 23 March 2012 (mimeo).

⁷ The term relates to debates about the topic conducted in the field of collective healthcare (see Luz 1996).

term, which was recently established - integrated and complementary practices. More than differentiating them, as I demonstrated in other texts (2015c) it is necessary to show that a lot of work and bureaucracy (laws, decrees, state agents and regulations) is involved in the difficult task of transforming an alternative/complementary therapy into an integrative and complementary practice.⁸ To some degree, this passage, from alternative/complementary therapies to integrative and complementary practices synthesizes the process of making these practices official within the Unified Health System. I will now look at how and with what terms this process took place.

INTEGRATIVE AND COMPLEMENTARY PRACTICES

In September 2003 a commission of technicians, doctors and specialists in alternative/complementary therapies was formed by Brazil's Ministry of Health to produce a national healthcare policy about the issue. Nearly two years later, in February 2005, this commission prepared a draft of the proposed National Policy on Natural Medicine and Complementary Practices, and submit it to technical chambers of national councils, state and municipal healthcare secretariats. Months later, in September, the document was presented in an ordinary meeting of the National Council of Health (CNS) and to its Commission on Sanitary Inspection and Pharmacology. In these two bodies, the policy was approved with some technical restrictions and others concerning the title of the policy. Carmem De Simoni, who participated in the group responsible for the preparation of the policy and who later, in the implementation period, was its first coordinator, commented on the problem raised by the National Healthcare Council in relation to the name initially proposed for the policy and the solution found to resolve it:

“Until then the name was the National Policy for Natural Medicine and Complementary Practices. When it reached the Council [CNS], the name medicine was not approved. This was because of the same questions raised about Chinese medicine. In the end, it did not pass. They said: ‘AH! You want to pass the policy?’ Yes, we do. ‘Then you must change the name!’ We said, ‘very well, we will’. Well, then we entered a small room, 5 people, and we began to think of a name. At some point [someone] entered and said, ‘but this is taking too long. Why don’t you use integrative practices?’ And that’s how it happened. It was Divaldo Dias who entered that room and gave the name to the policy. And it was a very good name!”(Carmem De Simone, interview, May 2013)

With the new name and with the technical changes incorporated to the text, the National Policy of Integrative and Complementary Practices was approved by the National Healthcare Council in February 2006 and the decree that established it was published on May 3 of that year.

⁸ I reiterate that this is a precarious solution and clarify that I do not use the term *alternative/complementary therapies* to fix the therapeutic practices that are not regulated by the state in this pairing of specific opposition or in the regimes of configuration that each one of the terms (alternative and complementary) admit. Here, the terminology *alternative/complementary* was the way I found precisely to indicate the multiverse character of the configurations that these therapies have. It is also necessary to mention that there are cases in which state and municipal policies recognize as integrative and complementary practices some alternative/complementary therapies that are not identified as such by the official policy. For this reason I may also alternate in considering a specific practice as complementary and integrated or as alternative/complementary.

The somewhat anecdotal case about the choice of name for the policy is indicative of contingent decisions not always based on technical principles and bureaucratic rationalization of the state that accompany the development of public policies. I mention it here mostly to emphasize that the name of the policy, or the terms it uses, were a condition for the document's approval. And once enacted, the National Policy for Integrative and Complementary Practices established, based on these terms, a regulatory regime for the therapies that it describes. Below I will address each one of the words in the policy's title. To do so, I will use as an analytical recourse, some comparisons between the terms used in this policy and others that are used in other regulatory regimes for alternative/complementary therapies.⁹

PRACTICES AND MEDICINES: COMPLEMENTARY AND ALTERNATIVE

In mid-2009, the Doctor's Union of Rio Grande do Sul (SIMERS) filed a public civil suit against the Escola Superior de Ciências Tradicionais e Ambientais [College of Traditional and Environmental Sciences] (Escam), which operates as a center for education in natural medicine in the city of Porto Alegre. The suit says little about the content of the courses offered and is more associated to the use of the term medicine in the promotional materials for the services offered, even if they are always accompanied by the words traditional or natural. The term doctor according to the ruling of the appeals court judge, is only for those who have been educated and registered by the competent professional council.¹⁰ In one of his decisions the judge ordered that the school abstains from using the expression 'doctor' or 'medicine' in its propaganda.¹¹

Also in 2009 the doctor's union of Rio Grande do Sul launched an advertising campaign, broadcast on radio, television and in print media, with the following content:

"Considering the recent offering of courses in Traditional, Ayurvedic, Environmental, Chinese and Ecological Medicine among others, SIMERS informs: 1. There is only one form of Medicine. To practice it in the country, it is necessary to comply with the educational legislation and be registered in the Regional Council of Medicine. 2. Any other exercise of Medicine is illegal, a crime punished with a prison term, according to art. 282 of the Penal Code. (...) Truth is good for your health."¹²

The monopoly on the term medicine in Brazil has a broad trajectory, which goes hand in hand with the establishment of doctors as a professional category in the country. As other authors have shown, in the past century, the exercise of medicine and the title of doctor have been defended against charlatans, mediums, religious people, healers and many others who tried to appropriate them (see: Giumbelli 1997; Weber 2003; Maggie 1992). The case described is only one example of many in which the use of the terms was denied to holistic therapists. To it we can associate the imbroglio, mentioned by Carmem De Simone, about the denomination traditional Chinese medicine to designate the exercise of techniques and procedures not recognized by the Federal Council of Medicine in Brazil, for example.

⁹ In an attempt to mark the permanent tension between various social actors by the definition of the status of these therapists, I will use as a narrative strategy the term *alternative/complementary* therapies.

Considering this controversy, it is evident how the use of the term practices in the National Policy for Integrative and Complementary Practices is used to avoid the category medicine, for which doctors have a monopoly of use that is repeatedly assured by the state. To recognize the therapies as a practice was essential to the approval and legitimation of the National Policy for Integrative and Complementary Practices, situating it, at least in terms of its name – which is important – outside the marks that regulate medicine in Brazil. The change in name, from natural medicine to integrative and complementary practices was thus essential for the National Policy for Integrative and Complementary Practices to acquire the capacity to produce its own regulations about alternative/complementary therapies, without which these practices would be denounced for appropriation (of the terms) of medicine.

The notion of complementarity, in turn, is constantly used as an encompassing term that is capable of designating the broad set of therapeutic practices included by the policies for the integrative and complementary practices. To situate the therapies supported by and offered in the official SUS as complementary practices signifies establishing the integrative and complementary practices based on a specific mode of relation with that which they complement - biomedicine. In this case, complementarity does not describe something that pertains to the substantive content of the therapies, but is a category that expresses how these therapies should relate with other modalities of healthcare. There is, therefore, an hierarchical relationship implicit to the term and which, in a certain sense, is a counterpoint to the designation alternative therapies. The practices regulated by the National Policy for Integrative and Complementary Practices are complementary and not alternative because they must be allied to biomedical treatment and made compatible to it, and not be alternative to it.

If, on one hand, the category complementary submits the therapies/practices/medicines that it describes to the modalities of healthcare that are complemented by it, on the other, researchers who analyze the category have emphasized the incongruence or even inoperativeness of the ideal of complementarity in some situations (White 2014). This is because not all of the associations of therapeutic practices complementary to biomedicine allow maintaining the principle of complementarity, as a type of policy of harmonious coexistence between different forms of treatment. This is what Ruth Barcan suggests (2011) when describing the impossibility of articulation, for example, between therapies to increase fertility based on diets of detoxification from industrialized products and biomedical treatments for the same purpose which is linked to the consumption of allopathic medications.

In the National Policy for Integrative and Complementary Practices, complementarity is not a quality that varies situationally, that is, according to the capacity of the association of the therapeutic models used in a specific situation. More than that, it is a policy of complementarity that, by decree, should always prevail, regardless of the forms or principles of the therapies in question. When inscribed in the policy regime of complementarity, the therapies give up a claim, at least on the formal plane, to the possibility of becoming alternatives (to biomedicine, mainly). In addition to this distinction between the two terms – complementary and alternative – it is necessary to emphasize that the option for the first and not the second in the National Policy for Integrative and Complementary Practices is also related to the dense historic load that the idea of alternative therapies has in Brazil. This is because it is primarily associated to esoteric practices, with little scientific proof and low acceptance among healthcare professionals. Here I only want to emphasize that to avoid the category alternative also meant the possibility of at least in a first moment, shifting the integrative and complementary practices from the universe of esoteric new age references,

thus operating a new possibility for alignment of these practices, which come to be approximated to the field of legitimate and official medicine.

As I have argued, the terms practices and complementary used in the National Policy for Integrative and Complementary Practices are broad categories that inscribe the therapies to which they refer in a regime of legitimation and specific regulation. These terms say little about the characteristics of the therapies themselves. Instead, they establish how they should relate with other therapeutic modalities.

Integrative is the other term used to name the policy. I suggest that it has a differentiated status from the other two described until now because it does not only concern the relation between the integrative and complementary practices with biomedicine, but is also related to how these therapies are integrated to the SUS. At the same time, as I will show below, it is a term that is key for making reference, without being explicit, to an idea that is central to these therapeutic practices, that is: a holistic quality.

INTEGRALITY, SUS AND HOLISTICNESS

Brazil's Unified Health System was established in 1990 under decree law 8080 which presents the objectives, attributions, guidelines, organization and administration of the country's healthcare services. This document also established, in chapter II, the three fundamental principles of the system: universality, equity and integrality. The first refers to the universality of the access to healthcare services at all levels of assistance, the second concerns the guarantee of equality of healthcare assistance, without prejudice or privilege of any kind. I want to focus on the third principle, that of integrality, whose definition in the decree cited establishes it as the model of assistance, understood as the articulated and continuous group of preventive and curative actions and services, individual and collective, required for each case at all levels of complexity of the system. Integrality, in this configuration, is an attribute of the healthcare model that stipulates, at a first moment, the integration, for each act of care, of the different entities within the Unified Health System, for prevention of risks and harm to healthcare and recovery. Carmen Teixeira, who is a researcher at the Collective Healthcare Institute of the Federal University at Bahia, affirmed in a text presented by the Ministry of Health:

"An integral model, therefore, is that which has establishments, care providing units, trained personnel and the resources needed for the production of healthcare actions that range from nonspecific actions for promoting health in defined population groups, to specific actions of environmental, sanitary and epidemiological inspection aimed at controlling risks and damages, to actions of assistance and recovery for sick individuals, or actions for the precocious detection of disease, or actions of diagnosis, treatment and rehabilitation." (Teixeira 2011, 7-8)

Beyond the strictly formal marks of the principle of integrality in the Unified Health System, established by law 8080, this category has a long political trajectory in the struggle for public healthcare services in Brazil, and also an academic one, having been the main analytical focus for many research projects.

The origins of the debate about the theme in the country relate to the history of the Movement for Sanitary Reform, which during the 1970s and 1980s, embraced different movements of struggle for better living conditions and better conditions for work in

healthcare and for the formulation of specific care policies for users (Pinheiro 2006, 255). When understood based on these movements, integrality concerns a type of amalgam-concept, as suggested by Ruben Mattos (2006, 46), which does not “seek to make a final definition, given that by establishing a definition we can abort some of the meanings of the term and in this way silence some of the questioning from social actors who struggle with us for a more just society”. For Kenneth Camargo (2003) the lack of a true definition of “integrality” is simultaneously a weakness and an opportunity for the category. This lack of definition appears to be accommodated in the affirmation of another researcher of the issue, José Ricardo Ayres (2006, 11): the principle of universality drives us to construct access for everyone, that of equity requires guaranteeing everyone to meet each one’s needs, but integrality challenges us to know and do “what” can be realized and “how” in healthcare to universally respond to each person’s needs.

Considering the recognition of the non-definition of the term, the analytical solution proposed by authors such as Ruben Matos (2006) has been to identify the uses and therefore the meanings of integrality situationally. I revive these considerations about the category of integrality to treat the term integrative which is part of the name of the National Policy for Integrative and Complementary Practices. Although the terms are not necessarily synonymous, the use of the category integrative in the National Policy for Integrative and Complementary Practices relates, at times, to integrality, as a principle of the SUS. In this sense, integrative appears to be another consequence of the undefined character of integrality.

The term integrative was incorporated to the National Policy for Integrative and Complementary Practices by the suggestion of one of the members of the National Council of Health, during the approval process for the policy. At that time, according to the minutes of the council’s 160th meeting, Francisco das Chagas Monteiro presented, in name of the Federal Council of Medicine, the suggestion:

“To substitute the term “Policy for Natural Medicine” for “Policy of Integrative Medicine”, which consists of medicine that uses conventional scientific knowledge aggregated to traditional knowledge (millenary or centenary), which is also scientific, excluding alternative practices based on creed, myths and magic and is associated to complementary therapeutic models, such as acupuncture, homeopathy and phytotherapy, in addition to propaedeutic models such as anthroposophic medicine.”¹³

Integrative, in this case, refers to the quality of a practice that integrates scientific and traditional knowledge, maintaining them, however, free of creeds. The suggestion was accepted and the term was incorporated to the title of the policy. In the text of the decree, however, and for the first national coordinator of the National Policy for Integrative and Complementary Practices, the meaning attributed to it is far from that proposed by the council member.

“This idea of integrative is ambivalent. First it is the principle of integrality of the Unified Health System, which is the vision of a policy that tends to comprehend the social, economic and cultural insertion of the creature in society. But together and simultaneously, integrative is also the holistic vision that these therapies have about the individual. This is there in the policy.” (Carmem De Simone, interview May 2013)

¹³ Source: 160th meeting of the CNS. Available at: <http://goo.gl/Bo3geB> (consulted on 14/01/2014).

The first dimension mentioned by de Simone appears at the very beginning of the presentation of the National Policy for Integrative and Complementary Practices, written and signed by the then minister José Gomes Temporão:

“In compliance with its responsibility to coordinate the SUS and establish policies to guarantee integrality in healthcare, the Ministry of Health presented the National Policy for Integrative and Complementary Practices within the SUS, and whose implementation involves justifications of a political, technical, economic, social and cultural nature.” (Brasil 2006, 4)

In this plan, the association between the Policy for Integrative and Complementary Practices and the principle of integrality of the Unified Health System is based on the characteristics of the policy itself.

In other portions of the document, however, this meaning is shifted and is used not to justify the National Policy for Integrative and Complementary Practices in the SUS, but to refer to how subjects treated by the integrative and complementary practices are understood as integral beings. In other words, integrative/integrality is no longer a quality of the National Policy for Integrative and Complementary Practices and becomes the perspective by which the user of the policy is conceived by the therapeutic practices the policy promotes.

“Upon acting in the fields of prevention against harm and the promotion, maintenance and recovery of health based on a model of humanized care focused on the integrality of the individual, the National Policy for Integrative and Complementary Practices contributes to strengthening the principal foundations of the SUS.” (Brasil 2006: 7)

“Considering the individual in his global dimension (...), the National Policy for Integrative and Complementary Practices corroborates to the integrality of healthcare (...).” (Brasil 2006, 3-4)

“Integrative and Complementary Practices are those for the promotion, protection and recovery of health, which presuppose users/patients in their physical, mental, emotional, social, environmental and spiritual integrality.” (Rio Grande do Sul 2014, 15)¹⁴

The categories of integrality and integrative that focus on the subject is thus approximated to a concept that is central to the alternative/complementary therapies: holism. In terms of the differences in the understanding about how holism can be therapeutically addressed (Kemp and Lewis 2007, 119), the use of the term indicates an opposition to medical therapies and perspectives that conceive the possibility of treating subjects in a fragmented form by specialists in a single part of the body.

What is at stake, therefore, is to observe how the category integrative, used in the National Policy for Integrative and Complementary Practices, operates on at least three levels. First, it is related to the evaluations that the National Council of Health made about the policy. Originally, according to the initial suggestions of the members of this council, the integrative character of the National Policy for Integrative and Complementary Practices refers to the integrating quality of these therapeutic practices that could combine traditional and scientific knowledge. In the text of the policy, however, integrative is associated to the principle of integrality of the Unified Health System, so that the National Policy for

¹⁴ The last portion was extracted from the state plan for integrative and complementary practices (PEPIC) of Rio Grande do Sul and expresses that the association between *integrality* and the holistic mode of treatment of the subject under the policies for the integrated and complementary practices is not restricted to the National Policy.

Integrative and Complementary Practices would find foundation and legitimacy in the very terms that establish the offer of public healthcare in Brazil. There is a third meaning that overlaps these two meanings, which relates the categories integrative and integrality to holism. I opt to make visible these three overlapping meanings without suggesting that one or another has acquired definitive form, thus emphasizing precisely what is undefined in these categories.

The version of the term integrative/integrality as holism also serves here to explain how, based on the terms used in the policy, a principle central to the alternative/complementary therapies according to the new age literature is developed without turning to the history of the countercultural movement but, to the contrary, appeals to the more formal aspects of Brazilian public healthcare. In the next section I will address another configuration of the alternative/complementary therapies in their official form, based on the terms used by the World Health Organization.

THE PROMOTION OF TRADITIONAL MEDICINE AND OF ALTERNATIVE/COMPLEMENTARY THERAPIES BY THE WHO

In the realm of the World Health Organization, two broad categories are those most used to designate the non-biomedical therapies, traditional medicine and alternative and complementary medicine. Although since the mid-1990s official documents from the agency have referred to these practices in a way that establishes equivalence between the terms, and use the initials TM (traditional medicine)/CAM (complementary and alternative medicine), these categories have specific genealogies in the discussions at the WHO. To explain the variations between them in the context of the legitimation and regulation of the use of alternative/complementary therapies by the WHO serves not only to demonstrate how the Brazilian policy for integrative and complementary practices accompanies similar processes in other countries, but also helps to understand the WHO's motivations for promoting these therapies.

One of the first registers of the term traditional medicine in the WHO documents was made in September 1978, at the time of the first conference on primary care, held in the city of Alma Ata, which was then part of the Soviet Union. Although it contained guidelines of various kinds, the final report of this conference was significantly marked by the context of the Cold War and by the systematization of data that express the unequal offer of healthcare technologies, professionals and hospital institutions in various countries of the world. It was based precisely on the recognition of the unavailability of these resources to two-thirds of the world's countries that the WHO identified traditional medicine as an action in healthcare and recommended the formulation of national policies and regulations that refer to the use of traditional medicine of proven effectiveness and exploration of the possibilities to involve those who hold traditional knowledge in primary healthcare activities, providing them corresponding training.¹⁵

Thus, if on one hand, this recognition would contribute to the legitimation of traditional knowledge about health and disease by an agency for global governance, on the other, this

¹⁵ Source: WHO, Conferência Internacional. 6-12 Setembro 1978 – Cuidados primários de saúde: declaração de Alma-Ata. Lisboa: Gabinete de Estudos e Planeamento 1978.

action is associated to the recognition of the scarcity, in certain parts of the world, of human and technological resources needed to provide healthcare, according to the precepts of biomedicine. In this sense, recognizing traditional medicine as a mode of healthcare established the conditions for the WHO to extend its own regulatory capacity to the more than half the planet that at the time did not have the healthcare facilities and institutions upon which the global agency could have influence.

According to the WHO, traditional medicine is the sum total of the knowledge, skills, and practices based on the theories, beliefs, and experiences indigenous to different cultures, whether explicable or not, used in the maintenance of health as well as in the prevention, diagnosis, improvement or treatment of physical and mental illness. By the characteristics of its definition and by that which I previously described, it is observed that in this configuration, the exercise of traditional medicine, according to the WHO, occurs mainly outside the West and far from the global north, that is, it is concentrated in the poorest parts of the world. In addition to the geographic perspective, which associates traditional medicine to poor or developing countries, two other characteristics can be gathered from the concept and documents developed by the WHO about the issue. First, traditional medicine is part of a cultural system and, second, these practices are millenary traditions, dating back to before the development of modern Western medicine.

Based on culture, historically situated in a distant past and geographically far from the West, the exercise of traditional medicine appears to be well summarized in the passage below, taken from the document WHO Traditional Medicine Strategy 2002-2005:

“A variety of indigenous TM systems have also been developed throughout history by Asian, African, Arabic, Native American, Oceanic, Central and South American and other cultures. Influenced by factors such as history, personal attitudes and philosophy, their practice may vary greatly from country to country and from region to region. (...) Traditional medicine may be codified, regulated, taught openly and practiced widely and systematically, and benefit from thousands of years of experience.” (WHO 2002, 7)

Considerations like these lead one to believe, as Waleska Aureliano (2011, 175) affirmed, that these practices are static or that they have not undergone significant changes over their history. These winds up characterizing traditional medicines based on stereotyped notions that reify them as millenary or ancestral practices that survive the advances of science.

As I mentioned earlier, traditional medicine is not the sole category used by the WHO to deal with therapeutic practices that are not aligned with Western biomedicine. During the 1990s, and particularly in the decade of 2000, it came to be associated to the term complementary and alternative medicine. Although articulated in some documents as if they are synonyms, this second category concerns the healthcare practices conducted in developed countries that do not share the same epistemological and therapeutic principles as biomedicine.¹⁶ The geographic link of alternative and complementary medicine with the developed countries, as well as the genealogical contrast of the category with that of traditional medicine at the WHO, appears explicitly in a document from the global agency about the use of non-hegemonic therapies:

¹⁶ In the WHO documents *Complementary and Alternative Medicines* are defined as “a broad set of health care practices that are not part of a country’s own tradition or not integrated into its dominant health care system” (WHO 2001).

“TM is widely used and of rapidly growing health system and economic importance. In Africa up to 80% of the population uses TM to help meet their health care needs. In Asia and Latin America, populations continue to use TM as a result of historical circumstances and cultural beliefs. In China, TM accounts for around 40% of all health care delivered.

Meanwhile, in many developed countries, CAM is becoming more and more popular. The percentage of the population which has used CAM at least once is 48% in Australia, 70% in Canada, 42% in USA, 38% in Belgium and 75% in France.” (WHO 2002, 5)

The contrast can be seen, at least in the original sense, between the concepts used by the WHO to designate the non-hegemonic therapeutic practices. First, traditional medicine is associated to contexts in which the offer of healthcare treatments is scarce and has little diversity. The second, complementary and alternative medicine, to the contrary, is associated to the offer of healthcare modalities that are alternatives to the biomedical hegemony. On the state level, the offer of complementary and alternative medicine would express the consolidation of the plural character of medical systems available in the West, while traditional medicine would be the cultural manifestation of regions with scarce and poorly diverse resources.

Also in relation to the two categories, it is worth emphasizing that little by little, in the realm of the WHO, they come to not necessarily qualify the therapeutic practices, but to characterize the relationship between a therapy and the context in which it is used. For the WHO, traditional Chinese medicine, for example, when used in China is an example of traditional medicine. When translated outside its culture of origin, however, and applied in Brazil or the United States, for example, it becomes an alternative and complementary medicine. It is this relationship that guarantees the affirmation, reiterated in the WHO documents, that traditional medicine and complementary and alternative medicine are interchangeable terms. Given that the identification of the therapies with these categories are unstable and provisional. On one hand, I recognize that this provisional character of the tie between the therapies and the categories traditional medicine and complementary and alternative medicine can relativize the binary quality that associates non-hegemonic practices of medicine in developing countries to traditional medicine and those realized in developed countries to complementary and alternative medicine. On the other, I affirm that this relativization does not make invalid the pertinence of identifying the configurations of power that cause each one of these categories (traditional medicine and complementary and alternative medicine) to emerge in the WHO.

Beyond the possibility of being used as synonyms, as affirmed by the WHO (WHO 2002, 2), these two categories also converge in that they use biomedicine as their principal element of reference and in the recognition that the fundamentals and exercise of biomedicine have no culture, time or space, or that these factors do not matter. If, in the original elaboration of these categories (traditional medicine and complementary and alternative medicine) there is an effort to establish a symmetry between the different forms of medical knowledge (which includes biomedicine), this effort involves an attempt to affirm that traditional medicines are culturally located forms of therapeutic medical practices, without, however, submitting biomedicine to the cultural localization of its traditions.

Once recognized and associated, traditional medicine and complementary and alternative medicine become the object of attention of a special department of the WHO, which since 2002, regularly publishes documents with goals and programs related to these therapeutic

practices. In one of the more recent publications about the theme, WHO Traditional Medicine Strategy 2014-2023, the WHO established four central objectives:¹⁷

“policy — integrate TM within national health care systems, where feasible, by developing and implementing national TM policies and programmes.

safety, efficacy and quality — promote the safety, efficacy and quality of TM by expanding the knowledge base, and providing guidance on regulatory and quality assurance standards.

access — increase the availability and affordability of TM, with an emphasis on access for poor populations.

rational use — promote therapeutically sound use of appropriate TM by practitioners and consumers.”
(WHO 2013, 11)

In the same document, Brazil’s National Policy for Integrative and Complementary Practices is mentioned as one of the exemplary experiences of integration of traditional medicine and complementary and alternative medicine in the national healthcare system.¹⁸ Equally exemplary, according to WHO, are the policies adopted in countries such as Belgium, Canada, Cambodia and Australia. Although the list with detailed descriptions about the experiences with the use of traditional medicine and complementary and alternative medicine is restricted in this document,¹⁹ the broader data it presents gives an idea of the scope and number of countries that have adopted specific policies to regulate and introduce these therapies in their healthcare systems. In 2012, 119 countries had regulations about traditional medicine and complementary and alternative medicine, while 69 have specific public policies to guide and promote the incorporation of these practices in their healthcare networks. These numbers are part of a historic series that since 1999, indicates a progressive increase in the number of countries that legitimate and regulate the use of alternative/complementary therapies.

Although the data found in these reports can be analyzed from different perspectives that are capable of presenting distinct forms of grouping the countries that produce national policies about complementary and alternative therapies, I highlight the presence of the variable culture, which was cited in the analysis of the concept of traditional medicine, to explain one of the differentiating perspectives of these policies. My suggestion is that it is possible to distinguish the various policies aimed at traditional medicine and complementary and alternative medicine based on the public that can access them. This is because, in Latin American countries, for example, most of these policies compose a broad range of actions based on the principle of interculturality. In name of recognition of cultural diversity and of the right to medical care according to individual beliefs, interculturality as a principle suggests, for example, that indigenous populations can demand that their care in hospitals, clinics and medical offices be associated to rituals and procedures from their own cosmology. This care, however, is not available for the entire population, but is restricted to subjects who

¹⁷ The document uses only the term traditional medicine. In its initial paragraph, however, the WHO clarifies that it understands there to be an equivalence between the term and alternative and complementary medicine.

¹⁸ The projection intended by the Ministry of Health with the National Policy for Integrative and Complementary Medicine should not be underestimated. The document was translated, printed and made available electronically in Portuguese, English, Spanish and Mandarin. Moreover, in 2008, the I International Seminar on Integrated and Complementary Practices was held, with participation of representatives from Cuba, Mexico, China, Italy, and technicians and members of agencies such as WHO and the Pan American Health Organization.

¹⁹ For an extensive overview from the WHO about the situation of traditional medicine and complementary and alternative medicine policies among its member countries (see WHO 2001).

are culturally identified with these practices. Contrary to these policies restricted to specific cultural groups are those like the National Policy for Integrative and Complementary Practices that have as a principal characteristic the universality of the offer and access to complementary and alternative therapies (see WHO 2001).

The WHO report about traditional medicine describes the Brazilian public policy as an exemplary model for integration of non-hegemonic therapeutic practices in national healthcare systems, but the policy does not legitimate or regulate, for example, healthcare actions aimed at traditional populations, and it does not address the action of midwives in the services of the SUS. The option for this model for the policies of the integrative and complementary practices certainly creates tensions. In Rio Grande do Sul, when I accompanied the process for elaboration of the state policy for integrative and complementary practices (see Toniol 2015c), technicians from the secretariat of health, linked to the healthcare services for the black population²⁰ requested a meeting with the commission responsible for the state policy for integrated and complementary practices. The request was not granted by the commission with the justification that the policy was being prepared for the entire state network of the Unified Health System and not for specific population groups.

RETURN TO A NEW AGE: IN CONCLUSION

I began this text stating the possibility to reflect on the limits of the new age as an analytical resource for understanding the current situation of provision and use of alternative/complementary therapies. Although in other studies (Toniol 2015a and 2015c) I have mobilized the historic references of this phenomenon and also addressed its analytical dimension, here I opted to treat the theme from a reversed viewpoint. That is, I raised a topic that is systematically associated to the new age to point to some of the limits of this perspective. In sum, my argument was that the possible association of some alternative and complementary therapies with counter cultural movements does not justify the deliberate use of the analytical language of the new age to frame and describe these practices. In this sense, what I did in this text was to present a set of other configurations for the provision and use of the alternative/complementary therapies that remain outside the field that is usually described as new age. I thus worked with the expectation that texts such as these can help to establish a principle of precaution, which from a methodological perspective, signifies calling for the analyses about alternative/complementary therapies to invest in describing the historic and conjunctural configurations that make these practices possible, without presuming the new age to be an absolute *a priori*.

This recommendation is necessary given that the literature dedicated to the theme appears to have left us accustomed to identifying any mention of alternative/complementary therapies as the expression of a trait inherited from religious, moral and aesthetic sensibilities of subjects and groups committed to the esoteric principles of the Age of Aquarius and with counterculture ideas.²¹ To make this warning does not imply abdicating a dialog with new age research. It involves indicating my effort to not stabilize the associations described here in a

²⁰ In the structure of the Secretariat of Healthcare of Rio Grande do Sul there is a sector, which is part of the Department of Healthcare Actions, that is specialized in healthcare for the black population.

²¹ Among the exceptions to this trend I highlight the work by Koch and Binder 2013.

category that appears to engage more the social scientists of religion than the subjects observed. Thus, what comes to be at stake is to not assimilate the various cases of offer and use of alternative/complementary therapies to a specific and univocal analytical line, which establishes their contours and characteristics by making them part of an ontological principle that transcends the situations observed. Alternatively, it involves reinforcing the need for studies about the topic that emphasize its variations, making the task of describing how? In what terms? and in what configurations? a constant analytical principle.

Chapter 545

THERAPEUTIC DIVERSITY AND PUBLIC HEALTH POLICIES AMONG VULNERABLE POPULATIONS: A STUDY IN BAHIA, BRAZIL

Fatima Tavares^{1,*} and Carlos Caroso^{2,†}

¹Universidade Federal de Rio de Janeiro, Rio de Janeiro, Brasil

²UCLA, Los Angeles, California, USA

ABSTRACT

The authors refer to issues involving health care policies in municipalities that surround the Bay of Todos os Santos (Bahia). It is initially presented some indicators of the Family Health Strategy (ESF) – the national public policy mediated by local implementation, and the main primary care program and disease prevention available in the country – which proposes general procedures about the health of the target population. Recognizing and articulated to some of the municipal health indicators, it highlights some state initiatives around two national health policies: the “National Policy of Comprehensive Health of the Black Population” and the “National Policy of Medicinal Plants and Herbal Medicines,” with special care for the impacts on the populations in situations of socioenvironmental vulnerability of the region. In the case of policy for black people, in addition to the high consideration given to the Afro-Brazilian traditional knowledge, the guidelines also turn to the minimization of inequalities in access to health services for this segment of the population. The policy of medicinal plants and herbal medicines is articulated to broader regulation of the National Integrative and Complementary Practices Policy (PNPIC), which does not focus on a specific segment and has as one of its guidelines the “encouraging of the insertion of Integrative and Complementary Practices at all levels of care, with emphasis on primary care,” thus stimulating the diversity of therapeutic practices in the SUS. Presenting some challenges around the “coexistence” between universalizing guidelines of ESF, in one hand, and of “recognition” policies of the differences in another hand, it will indicate clues to understanding of the processes of recognition of the high value of the knowledge of

traditional populations indicated by those policies, to the extent that the interlocutors of these policies and diverse opinions involved in the two fields of argumentation are not always the same.

Keywords: public health policies, vulnerable populations, therapeutic diversity

INTRODUCTION

Some of the challenges posed by public health care policies in municipalities¹ in the area of the *Baía de Todos os Santos*², or, simply *Baía*, is the subject of the discussion and analysis in this chapter. More specifically, we address to the difficult relationship between the universalization of biomedical care and the promotion of therapeutic diversity, with the aim to understand which forms of relationship have been interwoven amongst those public policies in this specific context.

With the objective of conducting the proposed analysis, we have taken some indexes of the Family Health Strategy-ESF³ (this is the government agency which defines and formulates the national orientation policy for implementation by the municipalities, resulting in the main program of primary health care and disease prevention available in the country), based on the general questions about the characteristics of the one which is the universalizing health system. With this purpose, we will focus on two national health sub-policies, which are represented by the “National Policy on Integral Health of the Black Population,” and the “National Policy on Medicinal Plants and Herbal Medicine,” we will focus on their initiatives and dilemmas, as well as their impact over the populations in situations of socio-environmental vulnerability in the area we have been conducting our studies.

LOCAL LEVEL HEALTH CARE

Since the late 1990s, new dimensions of health care have been gaining prominence in ESF. These range from normative guidelines valid throughout the national territory, to local arrangements involving management, pedagogical and therapeutic practices disseminated by different segments and professional and community agencies involved with health care in various ways. These orientations are so much more visible when we focus in historical perspective issues that concern the use of health services by these populations since the implantation of SUS. The expansion of health care provision by the Brazilian State, initially through the Program of Community Health. Agents (PACS), and latter by the ESF, did not necessarily result in the reduction of the role and importance community “traditional” knowledge and local health practices; on the contrary, they are transformed, they are

¹ *Municípios*, which stands for municipalities, are the local administrative units in each state of Brazil. They are further divides in *distritos*/districts. Each *município* has a main city, usually having its same name, and the districts will have diferente denominations. In the case that we are discussing there is one exception, represented by the insular município of *Vera Cruz*, whose main and administrative city is *Mar Grande*.

² This bay system encompasses the *Baía de Todos os Santos*, itself, the *Baía de Aratu*, the *Baía de Iguaçu*, and various river estuarine áreas, coves, and 56 islands of various sizes and shapes, being the largest the island of Itaparica. For further information on this see Caroso, Tavares and Pereira (2011).

³ ESF is the acronym for *Estratégia de Saúde da Família* in Portuguese, already translated for English.

contagious among themselves, taking on new forms in the face of the growing demand for rights in different segments of society, especially vulnerable populations and peoples. It is important to highlight that, given the territorial nature of health care, the ESF must deal with a context of diversity of practices that constitutes the therapeutic plurality to which we are referring⁴ to. Recent studies about the daily life of health teams has pointed to the coexistence of care networks that cross and transgress the territorialisation promoted by the ESF (Bonet and Tavares 2006, 2007 and 2008). Some of these are official (stemming from the very implementation of health teams in a territory), but there may also be a multitude of “unofficial”; they can be hierarchical and rhizomatic; visible, and invisible, in short, their striations make up a territory of varying densities (Deleuze and Guatarri 1995 and 1997). Thus, understanding the dynamics of this care policy requires the identification of the networks, identifying the already calibrated paths, the “paths” of the communities, through which it is possible to pursue care practices in its capillarity or landscape rhizomatic (Latour 2006).

Tensioning the hospital-centered model, the guiding principles of ESF that involve “integrality in health” have been challenged to mobilize an “expanded conception of care” that is not understood only within the limits of the doctor-patient relationship. For this, the ESF guidelines emphasize the need to decentralizing this relationship, disseminating care practices by health teams and seeking to overcome the “traditional” perception of the medical practice that intervenes on the non-situated individual. Categories such as family and community, considered “peripheral” in the “traditional” model, have been gaining relevance in this model (Fontes 2004, 129).

This redirecting of basic health care has been significantly contributing to the formulation of more effective public policies and intervention for various segments of the population, whose social dramas are strongly related to the processes of urbanization and modernization in peripheral regions of large cities, marked by intense inequality of access to public services and low quality of life, such as in municipalities on the edge or on the islands Baía that have been studied by the team of the research group *ObservaBaía*⁵.

The public health network available in the 14 municipalities that make up the research area (as highlighted in the map above), is made up of hospitals, polyclinics and/or specialized clinics and health posts and/or UBSs (Basic Care Health Units) and/or Family Health Units, as shown in Table 1, below. Considering the health care available infrastructure, the municipality that has the greatest need is Jaguaripe, which does not have a general hospital or specialized care facilities. Besides Jaguaripe, Maragogipe also does not have a general hospital and Salinas da Margarida does not have any specialized care (such as polyclinic). These noticeable deficiencies of the health care assistance in Jaguaripe, Salinas da Margarida and Maragogipe, which are contiguous municipalities located in the southwest portion of the Bay, forces a large portion of the population to seek for health care in neighbouring municipalities, such as Cachoeira, Itaparica, Vera Cruz and Salvador, resulting in overdemand and overloading of the latter's health care units.

⁴ In the daily routine of ESF it is possible to identify the “officialised” network by the territory of each one of them. This results from the systematic registration of the resident population within the scope of the work of a health team. A second network, also “official,” refers to each unit of registry, that is to say, the family units. It is at the intersection of these two networks that the therapeutic care interventions are carried out in the daily life of ESF professionals. On this question see Bonet and Tavares (2006).

Source: SESAB.

Graph 2. Proportion of population registered by ESF in Municipalities of Baía de Todos os Santos (2).

⁶ The data is presented in the two graphs for greater visual clarity. This index reflects in percentage the population registered by the ESF in the municipalities in relation to the total population of the municipality, based on the population registry of the area of coverage of the Family Health teams registered in the System of Information of Basic Attention-SIAB. The method of calculation is the population registered in the SIAB (model of attention ESF) in a certain location and period $\times 100$ / population in the same place and period. The data refer to December of each year. The municipalities of Candeias, Itaparica and Jaguaripe do not have data available for the year of 2015.

Percentages of attendance above 100% are identified in Cachoeira, São Francisco do Conde and Madre de Deus (in Maragogipe this plus difference is very small), indicating, therefore, the attendance of a non-resident population “officially,” who has been coming to these municipalities expecting to have access to health services. Madre de Deus is especially significant, as this situation occurs throughout the whole statistical series. Salvador (like other Brazilian capitals) and Simões Filho have the lowest percentage of coverage. The services available in the municipality of Madre de Deus, which “receives” many residents of neighboring cities and from the islands of the municipality of Salvador (due to difficulties in accessing the services of their municipalities), ends up “overburdened” with high rates of attendance, both in the system of primary care, and in emergency care, as observed in a previous study by the ObservaBaía (Caroso et al. 2014). Asymmetries like these give us clues about the problems experienced by the populations of these municipalities, but also indicate the extent of the capillarity of the health care networks that seek (and are successful) to transgress the official limits of the municipalities. In the municipalities of São Francisco do Conde, Candeias and the islands of the municipality of Salvador, the limits of municipal territoriality do not constitute a limitation for strategies for obtaining health care in other localities, which are problems more often observed in the small marginal districts than in the seat cities of the municipality (Caroso et al. 2014). Also among some marrons communities in the municipality of Cachoeira (which we have recently studied) similar dissatisfactions are observed about the proposed universality of ESF care (Tavares et al. 2017).

Taking into consideration these references, it is possible to emphasize the existence of a wide coverage of the ESF in whole of the municipalities around and in the interior of the Baía (except Salvador), although the quality of the service may present important variations. In order to understand better these questions that emerge from the previous discussion, we will identify and address to some points of tension between universalizing health care policies and the importance of therapeutic diversity.

HEALTH VULNERABILITIES AND HEALTH CARE POLICIES

The “National Policy on Black Population Health,” and the “National Policy on Medicinal and Phytotherapeutic Plants,” both emerge from within the discussions and formulations of health policies which consider and are directed to socially vulnerable populations. These initiatives from the part of the federal government can be found in the area where we have been conducting our studies, and their declared intention is to value the knowledge, populations, and people found in situations of social vulnerability, but they do so by means of different processes, because the people involved in the discussion do not always present the same characteristics, needs, and demands.

In the case of the social movements focused on black population health, besides the valorization of traditional knowledge, the demands also include the reduction of the inequalities of access to the health services for this segment of the population. In Salvador (and other Brazilian large cities) the demands are more heated within Afro-Brazilian religious communities, but little or no attention has been given to inequities in health care directed to

*quilombola*⁷ communities (such as those located in the municipality of Cachoeira, where we have been carrying out recent studies). This picture does not differ much from other regions of the country, where there is an urgent need for research and directed actions to implement differentiated policies aimed at *quilombolas* communities (Arruti 2008).

The “National Policy on Medicinal and Phytotherapeutic Plants” is articulated with the broader regulation of the “National Policy on Integrative and Complementary Practices” (PNPIC), which does not focus on a specific segment, but has as one of its guidelines the stimulus to plurality (which, of course, includes the ESF).

However, the inclusion of other therapies in the system hegemonized by agencies and practices of the professional health sector agencies face challenges and generates controversies for the valorization of community health sector agencies and practices (Caroso et al. 1997). As it can be understood from the text of the document itself, another guideline refers to “[...] articulation with the National Policy on Attention to Health of Indigenous Peoples and other policies of the Ministry of Health” (PNASI), as emphasized by Ferreira (2012, 267), “Instead of advocating the incorporation of traditional medicines into the national health system, PNASI recommends promoting the articulation of indigenous traditional medicines to health services.”

Within the limits of the Baía, these policies intersect in projects and actions implemented with the black population, precariously incorporating the *quilombola* communities. This is what we will see in more detail, as each of the policies is presented in the following parts of this chapter.

THE HEALTH OF BLACK POPULATION

The public debates involving the access of socially vulnerable populations to health care constitute the arenas of disputes concerning equity and respect, tolerance and religious visibilities, whose controversies present varying degrees of tension⁸. In this sense, the debate about the health of the black population constitutes a “field” of reflections and political interventions where ethnic-racial issues, health, Afro-Brazilian religions and the territoriality of the rural and urban *quilombos* intertwine.

The valorization of the therapeutic practices of *candomblé* configures an ambiguous arena, in which we find attitudes of religious intolerance (usually involving members of neopentecostais religions) amidst social life. Broadly speaking, the disputes that have as a reason the health of the black population are centered around the promotion of equity in health, taking a critical stance to the principle of universality which guides the SUS. Thus, several segments of the black movement demand a health policy that, at the same time, minimizes inequities and promotes the valorization of community-based therapies from African matrix. As Maio and Monteiro (2005) point out, the health policy for the black

⁷ *Quilombo* is the Brazilian denomination for maroon communities, being the *quilombolas* both the members of those communities and those descende of enslaved african populations.

⁸ Departing from the idea that “religion” and “society” are relational domains, rather than being self-referenced, it is necessary to consider the different modalities of configuration of Afro-Brazilian religions in the public space, which is to say that, in certain domains one can observe greater legitimacy than in others. This is the case, for example, of health practices, which can be discriminated against in contrast to festive and cultural practices that have been increasingly valued (Tavares and Caroso 2015).

population is resumed at the beginning of this century as an antiracist and affirmative action policy, which has been reinforcing identities of “racial conscience” with the participation of the State.

In the history of this policy, there is agreement between several authors (Maio and Monteiro 2005; Serra et al. 2009, 2010; Silva 2007), during the Government of Fernando Henrique Cardoso (1994-2002)⁹ Against Racism, Racial Discrimination, Xenophobia and Related Forms of Intolerance (2001), that iniquities in this area have gained visibility. In this context, the first initiative was held in 1996, the Roundtable on Black Population Health, an important meeting held in Rio de Janeiro, which brought together intellectuals, militants and technicians from the Ministry of Health. However, as Maio and Monteiro (2005), this event did not produce directed policies because it did not find, according to the document produced at that time, “technical justification for the creation of several specific public health programs for the black population, as some sectors in the sector intended” (p.2 document, apud Maio and Monteiro 2005)¹⁰. Even so, the balance of the event was to highlight the specificity of the black population's health, generating, in later years, other initiatives for its transformation into differentiated policies. Maio and Monteiro find a turning point in this debate at the Durban Conference in 2001: from then on “new actors took sides in favor of the implementation of “racial politics” (2005, 427). In the same year, the document “National Policy on the Health of the Black Population” was produced, with specific guidelines for the search for equity in health, in addition to demanding the official recognition of popular medicine of African matrix. At that very moment, it turned out clear that the universality of SUS was not enough to overcome racial inequalities.

During the Lula government (2003-2011) some actions have been implemented, such as the creation of the Special Secretariat for the Promotion of Racial Equality (SEPPIR) in 2003, enabling the following year, the constitution of Technical Committee for the Health of the Black Population. The 1st National Seminar on Health of the Black Population, in that same year, broadened the framework of action mentioned in the 2001 document, by valuing a diversity of actions, among which the promotion of health in the *quilombola* communities and recognition of the knowledge of Afro-Brazilians religions. Thus, a field of policies for the racialization of health is consolidated:

“The formation of the field of “black population health” occurs at a time when the debate about racism and the formulation of affirmative action programs are becoming increasingly visible in the Brazilian scene. It is the construction of a sectoral policy, with a racial cut, generating a process of differentiation and search of legitimation - in the scope of public health - of the grievances suffered by the blacks.” (Maio and Monteiro 2005, 438)

Parallel to the movement in the scope of the formulation of public policies, in the year 2003 the segments of the black movement also constituted the National Network of Afro-Brazilian Religions and Health, a fact which occurred during the II National Seminar of Afro-Brazilian Religions and Health, Held in Maranhão. In the historical record drawn by Silva (2007), the “Network” integrates diverse segments of civil society, seeking to valorize and leverage the traditional knowledge of these religions, as well as monitor governmental actions

⁹ As the authors point out, during that government a chapter on the health of the black population was included within the framework of the Interministerial Working Group for the Valorization and Promotion of the Black Population, created in 1995.

¹⁰ The exception was the Sickle Cell Anemia Program (PAF).

directed at these segments. This initiative is part of the anti-racism policies, and establishes partnerships with municipal health secretariats, as well as national seminars. According to the author:

“The Network develops several activities aimed at empowering the leaders of the Afro-Brazilian religious tradition for the exercise of social control of public policies. For this it counts on education and health professionals initiated or sympathizers of the *terreiros* that develop actions in the diverse nuclei spread by the country and *mães* and *pais de santo*¹¹ managing each nucleus of the Network.” (Silva 2007, 175)

Evaluating the Network's trajectory, the author points out that one of the most pressing challenges refers to religious intolerance within SUS: “We found from the beginning certain discomfort in the approach of the SUS to the *terreiros*” (2007, 176). This issue can be observed, for example, in the moments of professional training with the ESF teams, generating therapeutic and religious conflicts¹²:

“[The health agents] did not go into the *terreiros* to make routine visits, because they were scared or afraid that something would happen. The *terreiros* in turn complained that the PSF [currently ESF] did not meet them and thus did not comply with what was guaranteed by law, in the Constitution: the human right to health. Another challenge was to deal with religious intolerance, since most health teams are made up of people of other religions (Catholics and Evangelicals), who often make it difficult for the adepts to access the services offered by SUS. Health workers also complained that some supporters go against the guidelines prescribed by doctors and disrupt treatment. “The adepts trust more fathers and mothers of the saint than in us,” says the doctor.” (Silva 2007, 177)

The inequalities experienced by the black population, considering the principle of universality that guides the SUS and its policies, such as the ESF, qualifies the debate around the search for equity in health and not exactly through focal health policies such as Case of American society (Adorno et al. 2004). The experiences of inequality in treatment extend in different dimensions, as Lopes explains:

“In the case of health, the use of language as a means of maintaining and legitimating social and racial inequalities allows the creation of new mechanisms for the non-availability of a professional, adequate and equitable service. From the user's point of view, mechanisms are created and recreated for the non-perception or non-acceptance of negative attitudes on the part of the professionals. While they simulate egalitarian treatment,

¹¹ *Mãe de santo* and *pai de santo* is how the priests and priestesses of Afro-Brazilian religions are named in Brazil.

¹² Gomes (2010) describes an experience of partnership between an Afro-Brazilian *terreiro* and the Health Coordination of a Programmatic Area of the Municipality of Rio de Janeiro, where she was one of the active professionals. The request of the religious leader was aimed at the implementation of a vaccination unit within the space of the *terreiro* to serve the residents of the region. In the context of the *Posto* implementation process, the author reports that several complaints were presented by a group of women, many of whom were knowledgeable of professionals and users, such as “access difficulties, non-resolution assistance, racial prejudice, prejudices about poverty, maltreatment, prejudice related to the practice of Afro-Brazilian religion” (p. 665). One complaint, however, left the author intrigued: “invisibility,” which was only understood when the experiences of women were known. As the author points out with surprise: “The ‘invisibles’ had access to services, were attended to, accompanied, medicated and examined, but when we saw and heard them, we had the impression that they had never been seen.” (p. 665). The perception of invisibility, due to other difficulties presented, made the researcher recognize the fallacy of equity in health services provided to the population, producing contradictory speeches and interventions that denied poor women, black women and Afro-Brazilian religions their health demands. On the other hand, Lacerda et al. (2008), in a research related to evangelical ACS in the Northern Zone of Rio de Janeiro, point to the issue of religious intolerance as one of the issues addressed. According to the authors, it was observed that there is respect for the Afro-Brazilian religions in the daily work of these professionals, not interfering in the relations established with the families and houses visited.

they pretend not to perceive that they are being mistreated or pretend not to know that they do not have their needs satisfactorily addressed.” (Lopes 2005, 67, emphasis added)

Taking as reference a research carried out with users with hypertension, carried out in Rio de Janeiro and cited by Lopes, one can observe the capillarity of inequalities in health care: “The lack of cordiality on the part of the receptionist was cited by 4.5% of whites and 13.3% of blacks; By the auxiliary of nursing, 4.5% for whites and 5.4% for blacks; By the general practitioner, 4.5% among whites and 13.3% among blacks” (Lopes 2005, 67).

These problems also occur in the services found in the municipalities around the Baía. In a study of the relationship between *candomblé terreiros*¹³, public power and health policies in Salvador, Serra et al. (2010) point out different dimensions in the struggle for recognition of these groups: disputes over the religious dimension, territoriality involved in the management of urban space and the delay in recognizing Afro-Brazilian religions as “health agencies” (p.165).

Simultaneously with the process of constitution of the health policy of the black population at the national level, several initiatives took place in the city of Salvador, such as the 1st *Terreiro da Casa Branca* Health Fair, an event that was part of the activities of the I Seminar on Health of the Black Population¹⁴. Other editions of the fair took place in 2004, and in 2005, the Health Department of the Municipality of Salvador would refer to this project as a systematic activity (Serra et al. 2010, 168)¹⁵. In 2005, the Black Population Health Working Group was set up, an initiative linked to the newly created Municipal Secretariat of Reparation (SEMUR) in conjunction with the Municipal Health Secretariat (SMS). That same year, the SMS held a meeting with members of these secretariats and leaders of the *terreiro* with a view to the elaboration of propositions of activities. As a consequence of these initiatives, in 2007 the 1st Seminar on African Religions and Health was held with representatives of the Municipalities of Salvador and Lauro de Freitas, and the state government. The authors call attention to the central objectives of this meeting: the training of professionals to work in partnership with the *terreiros* and the training of *terreiros* agents (Serra et al. 2010, 169). Another claim of the meeting was the organization of an integrated district network of *candomblé terreiros* by the public health system. Serra et al. indicate that these objectives, still not very effective, sought to sensitize health professionals to the specificities of the *terreiros*, drawing attention to the problems of racism and religious intolerance. The following section synthesizes the intentions of the approach between religious leaderships and public administration from a double movement:

“The desiderata of the new policy that is tried to put into practice is double, as it is easily inferred from what has already been exposed: on the one hand, it is sought to contemplate effectively the people-of-santo in the actions of public health, giving him due Without discrimination; On the other hand, the objective of an alliance between government bodies and communities of *candomblé* is pursued, with a view to improving the health care of the black population (and the people in general).” (Serra et al. 2010, 170)

¹³ The *terreiro* is sacred ground and temple where all religious events happen. The older and more traditional ones are usually part of a *roça*, which includes not only the *terreiro*, but sacred trees and herbal gardens, *assentamentos*, and often a housing compound inhabited by some of the adepts.

¹⁴ The authors point out that the success of this seminar is that it mobilized several segments of the black movement to hold the First National Seminar on Health of the Black Population in 2004, held in Brasília.

¹⁵ Other health fairs were held in Salvador, such as the one that most recently took place in *Terreiro Jeje Savalia Karé Lewi* in June 2015 (Moreno Neto 2017).

On the one hand, health care; on the other, partnership. The terreiros can help in the capillarization of health policies, becoming “attention centers” as a result of the training of health professionals from these segments, seeking, therefore, policies directed and sensitive to the specificities of this population. However, the difficulties pointed out by the authors in the pursuit of this policy have come up against financial questions and religious intolerance. On this last point, Serra et al. (2010) affirm that this is a problem that is constantly approached in different forums that involve the candomblé leaderships and the public power.

“At the meeting just mentioned [I Seminar on African Religions and Health], this problem was clearly posed: community health and zoonotic agents refuse to perform health actions in the *terreiros*. In short, when it comes to meeting *candomblés*, they dodge the performance of routine actions that are their normal business.” (Serra et al. 2010, 171).

As the authors point out, if there are difficulties in the day-to-day care of the “*povo de santo*,” it is difficult to have a partnership, as the agents involved in this policy claim. The basis of this difficulty would be therapeutic prejudice (irrational and backward practices), diffuse racism and religious intolerance, the latter mainly driven by adherents of fundamentalist Pentecostal churches. On this issue, the consequences are severe for the Afro-Brazilian religions, as they clarify:

“One must note: religious intolerance spreading in Bahia is a cause of deprivation and suffering for an important segment of the population of the state, particularly its capital city: the *povo de santo*¹⁶, the priests and worshippers of the *orixás*¹⁷. It thus produces serious negative effects: on the one hand, it embarrasses the performance of a traditional system of action for health that effectively succumbs to the afflictions of many; On the other hand, prevents a more effective action by the public power in this field, in so far as it hinders a collaboration whose importance it is not possible to doubt.” (Serra et al. 2010, 173)

Allied to the difficulties surrounding religious intolerance, it is seen that the disposition of the public power towards the health of the black population is “much more rhetorical than effective” (Serra et al. 2010, 175). Serra et al. (2009), when the authors emphasize that the National Policy on Integral Health of the Black Population, approved in 2008, was assumed by the federal, state and municipal governments, but that in the government of Bahia has not yet been sensitive to the urgent need for a policy specifically directed at the health of the black population. The State Department of Health has agreed on a comprehensive policy of promoting equity, including blacks, indigenous people, homosexuals, *quilombola* communities, fishermen and *assentados*¹⁸, which fails to account for the specific health demands of blacks¹⁹. In this context, Serra et al. (2010) point to the fairs as the most successful experience between candomblés and the Municipal Government of the City of Salvador. They are different fairs from those held in other community spaces: in addition to the provision of services and other educational activities, there are still trade in products,

¹⁶ The adepts of religions of African matrix are known as *povo de santo*, which corresponding to saint's, in this case being *orisha's*, people.

¹⁷ Deities in the African matrix religions in Brazil.

¹⁸ *Assentados* are those rural workers who have benefited from the national agrarian reform program, getting access to land property.

¹⁹ Volochko (2009) presents several difficulties that involve the promotion of health in the *quilombola* communities of São Paulo, which are usually located in peripheral areas and economically poorly developed. In most municipalities, communities share the ESF services with nearby districts, creating numerous difficulties for the displacement of health professionals, high turnover and low qualification of managers. Poor and precarious facilities, as well as inadequate facilities to meet the population, complete the deficiencies.

dances, games, etc. These activities deserve great attention because they are elements that characterize the environment of *candomblé* and the sociability among its supporters and sympathizers.

If, on the one hand, we have, in the experience of the fairs, as occasional attempts at recognition of therapeutic diversity in a city like Salvador, on the other hand, the invisibility of *candomblé* therapies in health policy is evident in the composition of municipal health councils. The table below indicates the restricted participation of the Afro-Brazilian community in the councils in comparison with other religious segments (especially the Catholic ones): only in Salvador is an Afro-Brazilian representative found. This imbalance certainly results in important consequences in the construction of public policies directed to the “povo de santo.”

THERAPEUTIC DIVERSITY IN SUS

Ministerial Order 971/2006 – “National Policy on Integrative and Complementary Practices in the SUS” and the “National Policy of Medicinal Plants and Phytotherapeutics” - Presidential Decree 5813/2006 - finally came to recognize and stimulate therapeutic diversity and Practice in the field of public health care. Seeking to comply with WHO guidelines, the objective was the inclusion and access of the population to phytotherapy/medicinal plants, acupuncture, homeopathy and termalism/chronotherapy practices. The valorisation of

²⁰ Available in http://www1.saude.ba.gov.br/cib/conselhos_municipais.asp. Accessed on: 12 May 2017.

alternative, community and “traditional” knowledge constitutes a tripartite policy, with responsibilities distributed by the federal, state and municipal governments, in order to increase the resolubility of the public health system.

The implementation of these policies in Bahia has focused more specifically on the issue of medicinal and phytotherapeutic plants and has been mobilizing the efforts of UFBA professors and researchers through the teaching, research and extension center of the Faculty of Pharmacy (*Farmácia da Terra* /UFBA) and the FITOBAHIA/SESAB, nucleus of the state health department. According to Almeida (2011a and 2011b), who is the coordinator of both nuclei, the strategies for the incorporation of complementary practices in the SUS-BA goes through the valorization of traditional cultures, especially African religions and of the identification of limits and possibilities for the insertion of phytotherapy in the public health services. Regarding herbal medicine, the author identifies and enumerates three main lines of action: a) the insertion of phytotherapy in the scope of state health policy; B) the creation of the State Nucleus of Medicinal Plants and Phytotherapy (FITOBAHIA), and c) the designing and implementation of the State Program of Medicinal Plants and Phytotherapy (Almeida 2011b, 31).

According to this author, these objectives have been consolidated, emphasizing that in 2009, *Portaria* No. 1686, instituted the State Nucleus of Integrative and Complementary Practices of SUS and the Nucleus of Medicinal and Phytotherapeutic Plants, as an integral part of the first. In the initial phase of the project of medicinal and phytotherapeutic plants, the municipalities included have been Itacaré, Ilhéus, Itabuna, Palmeiras, Itapetinga, Juazeiro, Igrapiúna and São Francisco do Conde, which is the only municipality among those located around the Baía included in the program (Almeida 2011b, 31). She mentions some challenges which have to be dealt for the implementation of these policies, such as the acquisition of materials, the qualification of professionals, the acquisition of basic knowledge about these therapeutic practices among SUS professionals, managers and users, the need for participatory management, cooperation and national and international exchange and education, evaluation and further research (Almeida 2011b, 32).

It should be considered, however, that the policies of valorization of traditional practices such as those involving medicinal plants need to consider both the epidemiological profile of the populations and the specificities of the therapeutic practices that make use of native plants. Commenting on the formulation of legal frameworks²¹ for the regularization of medicinal plants in Brazil, Almeida and collaborators (2012) indicate that these “milestones” have been giving greater prominence to exotic plants, as can be seen in the last edition of the “Brazilian Pharmacopoeia,” in comparison with the 1929 edition. In this sense, the authors warn that:

“The state of Bahia is divided in 417 municipalities, and it is covered by divers biomes, such as the Atlantic Forest, the *caatinga*, the *cerrado*, the coastal zone vegetation and transition zone of the *cerrado-caatinga*, which justifies considering the epidemiological profile of each municipality, the native species present in each of those biomes, as well as the knowledge and health practices of the local population for the elaboration of the State Relation [of medicinal and phytotherapeutic plants] and Therapeutic Memento. Ethnobotanical surveys carried out in the *Recôncavo Vaiano* indicate that, unlike official lists, Afro-descent

²¹ As to the National List of Medicinal Plants of Interest to SUS (RENISUS) released in February 2009, which includes 71 species of plants, in addition to ANVISA regulations for registration of herbal medicines (RDC 14, October 31, 2010), resolution on (RDC 10, 03/10/2010) and normative instruction (IN-05/2008) of medicinal plants considered as a simplified registration.

communities preferentially use native species for medicinal and ritualistic purposes in the proportion of 52% to 28% of Brazilian legal landmarks.” (Almeida 2012, 244)

In the context of the Baía, the nucleus of UFBA (developing activities since 1995), in partnership with FITOBAHIA/SESAB, conducted in *São Francisco do Conde* a work of insertion of community therapeutic practices in the *Sistema Único de Saúde-SUS*²², through articulation of the health policies for the black population and of the herbal and phytotherapeutic plants. The implementation of this project took place through ethnopharmacological research, training of public network professionals and educational actions with the local population (according to news published on the Internet, the group cataloged more than 60 species of medicinal plants). The localities of the municipality served by the project were Muribeca (due to the large number of elderly) and the *quilombola* community of *Monte Recôncavo* (emphasis on therapeutic practices of African matrix), besides the seat district²³. For the implementation of the herbal medicine program, the UFBA nucleus developed activities ranging from theoretical classes, cultivation of medicinal plants at the Faculty of Pharmacy of UFBA, visits and research to popular fairs and *candomblé terreiros*, follow-up of popular initiatives such as “*Botica da Terra*.” This last project was initiated by a group of women from the suburbs of Salvador, which was stimulated by the city's archdiocese, which sought new practices in education, hygiene and health. The group started its activities in the 1980s, in the neighborhood *Alto da Terezinha*: in addition to several actions in education and health, the group had a home remedy center located since 1997 in *Pelourinho* (currently this project is deactivated).

As it can be seen, both from the situation in the State of Bahia and the Baía region, these policies are still incipient, insofar as they are restricted to a few municipalities and focus on the implementation of medicinal and phytotherapeutic plants. In a meeting of the state coordinators of integrative and complementary practices programs, held in 2011, in Brasília, Almeida (2011b) records the progress of this program in Bahia: only policy regulation. The author also indicates that actions have already been initiated to train professionals and to conduct orientation seminars for SUS users, but there is still no availability of resources for the implementation of the Pharmacobotanical Garden, the “Live Pharmacies” and the Herbal Medicines Processing Centers.

CONCLUSION

Returning to the characteristics highlighted in the two public policies which have been presented, one can identify as a common point the valorization of therapeutic diversity, however, through certain specificities. In policy designed for the black population, in addition to valuing Afro-Brazilian traditional knowledge, the guidelines also focus on minimizing inequalities in access to health services in this segment of the population, that's to say, a demand for “more” universalization “of biomedical care.” However, the policy of herbal and phytotherapeutic plants, which is articulated with the broader regulation of the “National Policy of Integrative and Complementary Practices” (PNPIC), does not focus on a specific

²² Unified Health System of Brazil.

²³ Information available on the website: farmaciadaterra.ufba.br.

segment and has as one of its guidelines the incentive to therapeutic diversity in scope (“inside”) of SUS.

The resumption of this discussion, based on the data on which is based this chapter, has led to the identification, as in practice, of some challenges involving the universal guidelines of the ESF, on the one hand, and the policies of “recognition” of the differences, drawing attention to the need to deepen the discussion and to understand these processes in close interrelation. The policies mentioned highlight processes of valorization of people’s knowledge in complex situations of social, economic and environmental vulnerability, since the policy interlocutors and the diverse opinions involved in the two fields of discussion are not always the same. These are challenges that make it difficult to understand the complexity of situations and, consequently, the need to argue in favor of giving isonomic treatment to the parties, differentiated by means of unequal treatments, that allow those who are in those situations of inequality pointed out in this text to overcome the deficiencies to which they are subjected in all aspects of everyday life, which includes formulation and implementation of affirmative action policies in health care²⁴.

²⁴ Nery Junior (1999, 42) argues that “giving isonomic treatment to the parties means treating equally and unequally the unequal, in the exact measure of their inequalities.”

Chapter 546

MUSSELS AS SENTINEL ORGANISMS IN METAL AND METALLOID CONTAMINATION SCENARIOS: ENVIRONMENTAL AND PUBLIC HEALTH RISK BIOINDICATORS

ABSTRACT

Among environmental pollutants, metals and metalloids are of particular concern due to their potential toxic effects and the ability to bioaccumulate throughout the aquatic trophic web. However, the simple measurement of chemicals levels present in the environment is often not enough to reveal the actual adverse effects of the contamination, making it necessary to also assess the biological effects of contamination on living organisms, applying bioindicators and biomarker measurements. Mussels have been recognized as one of the best sentinel organisms regarding aquatic environments and have been increasingly used in many worldwide environmental monitoring programs. This chapter will discuss the role of several mussel species in environmental monitoring programs, with emphasis on metal contamination, including metal bioaccumulation and biomarker investigations. In addition, the fact that these organisms may be an important contaminant transfer link to the human population and pose important public health risks will also be discussed.

Keywords: mussels, sentinel organism, metal contamination, biomarkers, oxidative stress, public health risks

INTRODUCTION

One of the major damaging effects in aquatic environments due to anthropic activities is contamination by chemical pollutants. These contaminants continuously enter the aquatic environment through inadequate waste disposal, incomplete removal by sewage treatment plants, and sewage dumped into water bodies without adequate collection and treatment. Among the many different environmental contaminants present in these ecosystems, those of greatest concern present environmental persistence, bioavailability, a tendency to bioaccumulate in the food chain and the ability to cause toxic effects, such as persistent organic pollutants (Jones and de Voogt, 1999), polycyclic aromatic hydrocarbons (Abdel-Shafy and Mansour, 2016), metals (Singh et al., 2011) and, more recently, emerging contaminants originating from substances used by the human population in daily life, such as pharmaceutical formulations and personal products (Burkhardt-Holm, 2010).

Among environmental pollutants, metals and metalloids are of particular concern due to their potential toxic effects and the ability to bioaccumulate throughout the aquatic trophic web (Censi et al., 2006; MacFarlane and Burchett, 2000; Miller et al., 2002), thus being the subject of many biomonitoring efforts.

Metal and metalloids enter aquatic systems through both natural and man-made processes. The natural processes that most contribute to their presence in aquatic environments are rock weathering and the erosion of soils rich in metals and metalloids, while the main anthropic sources are industrial and mining activities, domestic effluents, surface water runoff from areas cultivated in the presence of chemical fertilizers and agricultural pesticides, and atmospheric precipitation of ash or small particles from fires (Esteves, 1988; Jordão et al., 1999; Mortatti and Probst, 1998; Nriagu and Pacyna, 1988; Ramalho et al., 2000; Yabe and Oliveira, 1998).

In the aquatic environment, metals and metalloids are distributed in both the aqueous (water column and interstitial water) and the solid (suspended and sedimented) phase, as well as in aquatic organisms, with a dynamic exchange between these phases, varying from one ecosystem to another (Conceição, 2004). Aquatic organisms assimilate metals and metalloids from both the aqueous and solid phases, namely water and sediments and, especially, food. These elements may then accumulate in tissues in several orders of magnitude above concentrations found in the water column. Therefore, aquatic organisms are responsible for much of the dynamics of these pollutants in the aquatic environment. It is important to note that the effects of these pollutants can be toxic and/or lethal to all components of the biota, such as phytoplankton, benthos, fish, birds, and, finally, humans that feed on contaminated organisms (Canli and Atli, 2003; Fowler, 1982; Junior et al., 2002; Pfeiffer et al., 1985), through bioaccumulation and bio magnification processes.

METAL AND METALLOID TOXICITY

Metals and metalloids can be classified as essential, non-essential and toxic elements. Essential elements, when present in low concentrations, play an important role in organism metabolism. Non-essential elements and toxic elements, however, do not play any known biological functions. Increasing essential element concentrations, up to a certain range, lead to

improvements in organism development and metabolism. Above this range, these elements become toxic and, beyond a certain limit, lethal. Non-essential elements, on the other hand, are tolerated by the body to a certain extent and, if present above certain concentration limits, follow the same behavior described above, becoming toxic and then lethal to the organism. These differences are displayed in Figure 1.

Figure 1. Graphical representation of the relationship between essential and non-essential concentrations and their effects on organisms. Adapted from Galvão (2003).

Element toxicity also depends on the chemical form present, i.e., the bioavailable fraction. Some metals and metalloids, such as Cd, Pb, Hg and As, for example, are non-toxic in the forms of free condensed elements, while, when present in their cation forms and when bonded to short carbon atom chains, become toxic. The amount absorbed by the organism also influences element toxicity, since even essential elements can be toxic when absorbed above limits tolerable for normal organism metabolism, as stated previously (Baird, 2002; Melo, 2003).

Different metal and metalloid toxicity mechanisms have been described, including (i) enzymatic inactivation due to the high reactivity of divalent transition metals with the amino and sulfhydryl groups of proteins; (ii) metal competition with essential elements and their replacement in the enzymatic metabolism - Pb, for example, can replace Zn in several proteins that function as transcription regulators - and (iii) the “cocktail effect,” in which the excess of one element can cause the deficiency of another(s), such as the case of excess of Pb, that interferes in the absorption of Ca, Fe, Cu and Zn, for example (Förstner, 1989; Melo, 2003; Moreira and Moreira, 2004).

Thus, although the determination of metals and metalloids in tissues and organs of different aquatic organisms is an important method to evaluate metal contamination in aquatic ecosystems (Farkas et al., 2001), the simple measurement of metal levels present in the environment is often not enough to reveal the actual adverse effects of the contamination, making it necessary to also assess the biological effects of contamination on living organisms. This is performed through the use of bioindicators, also termed sentinel species, and biomarker measurements.

MUSSELS AS BIOINDICATORS CONCERNING ENVIRONMENTAL METAL AND METALLOID CONTAMINATION

Mussels are widely used as bioindicators for a number of aquatic contaminants, due to their sessile nature, which facilitates their sampling, their worldwide distribution, reasonable

size, known biology and ecology, and filtering feeding habits, leading to the absorbance and retention of solid particles and, consequently, any contaminant adsorbed therein (Lamparelli, 1987; Rainbow, 1995; Resgalla Jr. et al., 2008; Wallner-Kersanach and Bianchini, 2008).

These organisms are able to concentrate contaminants in their tissues and survive, and even, thrive, in contaminated environments and are, therefore responsible for part of pollutant dynamics in the aquatic environment. In addition, they concentrate environmental contaminants proportionally to external (water) concentrations, thus reflecting the contamination history of the environment and, because they settle on shallow water substrates, they are exposed to environmental factors on a local scale, allowing for the comparison of environmental contamination between different locations (Chase et al., 2001; Chou et al., 2004; Dame, 1996; Rainbow, 1995; Storelli et al., 2000; Sun et al., 2004).

Because of these characteristics, mussels have been recognized as one of the best sentinel organisms regarding aquatic environments and have been increasingly used in national and international environmental monitoring programs (Bellotto et al., 2005) for both freshwater and marine ecosystems. For example, the United States National Oceanic and Atmospheric Administration Mussel Watch Program, the nation's longest running continuous coastal contaminant monitoring program, has applied several *Mytilus* species, such as *Mytilus edulis*, *Mytilus californianus*, *Mytilus galloprovincialis* and *Mytilus trossulusto*, to evaluate the contamination status of US coasts (Binelli et al., 2015), while many other species have been applied as bioindicators for metal and metalloid contamination scenarios worldwide.

Several biomarkers have been routinely investigated in these contamination scenarios, in order to evaluate the potentially deleterious effects of metal and metalloids, which shall be discussed further ahead in this chapter. First, however, it is important to understand the subcellular and molecular effects of metal and metalloid exposure in living organisms.

SUBCELLULAR AND MOLECULAR EFFECTS OF METAL AND METALLOID EXPOSURE: REACTIVE OXYGEN SPECIES AND OXIDATIVE STRESS

One of the main deleterious effects of metals and metalloids are alterations in cellular redox regulation or oxidative reaction cycles, producing reactive oxygen species (ROS) and certain non-radicals derived from oxygen capable of generating free radicals, such as hydrogen peroxide and hypochlorous acid, which, in turn, may lead to oxidative stress (Buonocore and Groenendaal, 2007; Halliwell and Gutteridge, 2007).

Free radicals, like ROS, are small molecules with a short half-life that possess one or more unpaired electrons, characterized by high reactivity, sequestering electrons from neighboring molecules in order to become stable (Buonocore and Groenendaal, 2007; Halliwell and Gutteridge, 2007). The main ROS species are usually formed by the main oxygen metabolism route in the body, which is completely reduced to water, integrating four electrons at the end of the electron transport chain inside the mitochondria. The main ROS, superoxide anion, hydrogen peroxide and hydroxyl radical, are produced when the oxygen molecule is reduced, along with a smaller number of electrons along the respiratory chain.

The body, however, possesses natural ROS elimination systems, known as intracellular antioxidant defenses, which are substances that prevent, delay or remove oxidative damage

from a target molecule (Cogo et al., 2009; Halliwell and Gutteridge, 2007). When these antioxidant substances are present in amounts equivalent to ROS concentrations, the metabolism and cellular functioning of living organisms remain unchanged. However, situations where excessive ROS are being produced, and/or cases of failure of antioxidant defenses may lead to oxidative stress, caused by the imbalance between the formation rate of oxidant molecules and antioxidants in the body (Halliwell and Gutteridge, 2007). Oxidative stress may then lead to protein carbonylation, a process by which proteins can undergo reversible and irreversible oxidation and covalent modifications in their amino acids, modifying them into aldehyde or ketone groups, which are harmful to proteins, causing their aggregation, inactivation and degradation, and the produced ROS may interact with lipids, proteins or nucleic acids, resulting in various biochemical or genetic damages (Costa et al., 2002; Ghezzi and Bonetto, 2003; Levine et al., 1990).

The presence of metals and metalloid in biological systems in an uncomplexed form, not as protein co-factor or any other type of protective metal complex, can significantly increase oxidative stress levels (Dalle-Donne et al., 2006). In this context, certain redox-active metals, that undergo redox-cycling reactions, such as Cr, V, Co and Cr, are known to induce oxidative stress, causing damage to mitochondrial respiration (He et al., 2008; He et al., 2007; Valko et al., 2005), while other metals, such as Fe and Cu, are known to produce ROS by the Haber-Weiss (Equation 1) and Fenton (Equation 2) reactions (Barreiros et al., 2006).

The Fenton reaction occurs in the presence of metal ions and hydrogen peroxide, forming the hydroxyl radical, hydroxyl anion and leading to metal oxidation. In the Haber-Weiss reaction, metals can react with the superoxide anion through its reduction, generating molecular oxygen, and the reduced metal the reacts react with the hydrogen peroxide, generating the hydroxyl radical in the Fenton reaction (Leonard et al., 2004).

The generation of these radicals may lead to negative effects if organism defenses are overwhelmed. In this context, biomarker responses, meaning measurable alterations of any physiological, biochemical or behavioral steady state induced by an environmental change, against metal- and metalloid-induced oxidative stress are applied as early warning signs of the possible deleterious effects of these contaminants.

MUSSEL BIOMARKER RESPONSES AGAINST METAL - AND METALLOID-INDUCED OXIDATIVE STRESS

Mussel gills, digestive gland and haemolymph are regarded as excellent candidates for assessing toxic impacts of metal and metalloid exposure, due to their direct contact with the environment (water medium) and the fact that they are the center of metabolic regulations and metal transfer pathways to detoxifying tissues (Chandurvelan et al., 2013). Thus, biomarkers against metal- and metalloid-induced oxidative stress in these tissues are investigated in order

to detect early negative effects and allow for decision-making processes regarding these environmental contaminants.

In this regard, one of the main biomarkers established by monitoring programs developed and implemented in the European community to investigate contamination by metals and metalloids is the metalloprotein metallothionein (MT) (Bebianno et al., 1993; Garrigues et al., 2002; Sarkars et al., 2006).

Metallothioneins are a group of low molecular weight (6 to 7 KDa) metalloproteins (proteins that bind to metals), rich in cysteines and presenting heat stability. They display a high affinity for metal ions and play an important role in several biological functions, such as essential metal homeostasis and detoxification of both non-essential elements and essential elements present in excess in the organism (Freire et al., 2008; Monserrat et al., 2007; Motta, 2012; Sarkars et al., 2006; Viarengo et al., 2007). Their synthesis is induced through the presence of metal and metalloid cations in the body, and the thiol group (-SH) present in this metalloprotein's structure allows binding with these elements, restricting their bioavailability (Freire et al., 2008; Linde et al., 1999; Monserrat et al., 2007; Nicholson and Lam, 2005; Viarengo et al., 2007).

Usually, these proteins bind to 7 equivalents of divalent metal ions, through the formation of metal-sulfhydryl clusters (Figure 2) (Melendez et al., 2012; Motta, 2012), in which the order of affinity is usually $\text{Cd} > \text{Pb} > \text{Cu} > \text{Hg} > \text{Zn} > \text{Ag} > \text{Ni} > \text{Co}$ (Waalkes et al., 1984), although this may vary according to the bioavailability of the metals in the cell.

Figure 2. Metal binding sites present in one metallothionein molecule. "M" indicates metal ion binding sites. Adapted from UVED (2015).

Several metals have been shown to induce MT synthesis in mussels. For example, Mourgaud et al. (2002) observed that As, Cd, Cr, Cu, Hg, Ni, Pb and Zn concentrations were significantly correlated to MT in the mussel species *Mytilus galloprovincialis* mussels, while Purina et al. (2013) observed the same for Cd, Pb, Hg, Cu and Zn and MT in the freshwater mussel *Anodonta* spp. In another study, an increase in MTs in *Dreissena polymorpha* was shown to occur at relatively low aqueous Pd concentrations indicating that there is the need for Pd detoxification in these mussel, with significant correlations between MT and Pd associated with adverse effects on the mussels (Frank et al., 2008), while significant correlations were determined between MT induction and metal contamination in the green-lipped mussel, *Perna canaliculus*, indicating that different sampling sites were clearly distinguishable based on the metal contamination profiles and this biomarker response (Chandurvelan et al., 2015).

Tissue-specific responses have been reported for this biomarker, such as in the study conducted by Lavradas and collaborators with *Perna perna* mussels sampled from 3 contaminated areas in an extremely contaminated bay and compared to a reference site in southeastern Brazil, where the digestive gland was shown to be a better bioindicator for metal and metalloid contamination compared to muscle tissue (Lavradas et al., 2016). This was also observed in a study that investigated Cd and MT distribution in different tissues of the freshwater mussel *Anodonta woodiana* following Cd exposure. In this case, the authors report that Cd was distributed in all tissues in the concentration order of gills>mantle>foot>visceral mass>digestive gland, and that the highest Cd accumulation was found in the digestive gland, while MT levels in the gills and mantle increased significantly and were positively correlated to Cd accumulation in the different tissues (Li et al., 2015).

However, it is important to note that variations in MT isoforms may be present, in which one or more may contribute to metal detoxification, while others may not display a function in this regard, or may even be inhibited following metal or metalloid exposure. For example, in one study, *Mytilus edulis* specimens were exposed to Cd and Hg for 21 days and the gills, mantle and digestive gland were evaluated regarding MT isoforms. Size exclusion chromatography showed the presence of an MT monomer and a dimer in gills, of respective apparent molecular weight of about 12 kDa and 20 kDa, which were then resolved into five components by anion exchange chromatography in the gills of control or Hg-treated mussels, whereas a sixth isoform was isolated in the gills of Cd-exposed mussels. In the mantle of mussels, exposed or not, five isoforms were separated, and in the digestive gland of mussels exposed or not, six isoforms were separated (Geret and Cosson, 2002). In another study, different MT isoforms were observed in the digestive gland of control and experimentally Cd-exposed mussels in *Mytilus edulis* ($200\ \mu\text{g L}^{-1}\ \text{Cd}^{2+}$ and $400\ \mu\text{g L}^{-1}\ \text{Cd}^{2+}$; 20 days), where an induction of the dimeric form MT20 II was detected in the $400\ \mu\text{g L}^{-1}$ exposed mussels and an inhibition of the monomeric form MT10 IV was verified (Ciocan and Rotchell, 2004).

It is thus, important to investigate MT expressions in mussels through analytical techniques that allow for isoform differentiation, since different MT isoforms may contribute to different metal and metalloid detoxification mechanisms.

The glutathione metabolism is also extremely important in conferring protection against metal and metalloid toxicity.

Glutathione (γ -L-glutamyl-L-cysteinylglycine) (Figure 3). is a tripeptide with strong antioxidant capacity, determined by the reactive grouping of its cysteine, the thiol group (-SH).

This tripeptide acts directly or indirectly in many biological processes, such as in metabolic and transport processes, acting against the production of free radicals, in thiol homeostasis, maintenance of the redox balance of the cell, defense against xenobiotics and playing a central role in the biotransformation and elimination of electrophilic agents and protecting cells against the toxic effects of a variety of compounds. GSH is used as a substrate in conjugation reactions, catalyzed by glutathione S-transferase enzymes, but is also capable of participating in nonenzymatic conjugations with many xenobiotics (Aquilano et al., 2014).

Several studies demonstrate the induction of metal-GSH complexes in different organisms after exposure to these compounds, through the sulfhydryl group, such as Cu^{2+} and Fe^{3+} , that readily catalyze GSH oxidation, producing several free radical species (Rabestein et al., 1985; Stohs and Bagchi, 1995), and the Cu^{2+} reduction by GSH, that produces a stable Cu^{1+} -SG complex that impedes further redox cycling and leads to the generation of free

radicals (Corazza et al., 1996). Thus, it has been proposed that GSH is able to complex with metals and detoxify organisms soon after the entry of these elements into the cell, representing a first line of defense against metal cytotoxicity (Canesi et al., 1999).

Figure 3. γ -L-glutamyl-L-cysteinylglycine.

The glutathione metabolism also includes several glutathione-based enzymes, such as glutathione S-transferase (GST), glutathione peroxidase (GPx) and glutathione reductase (GR), which have also been implicated in metal and metalloid biomarker responses.

In this regard, research has investigated glutathione metabolism proteins and enzymes in mussels and their responses after metal and metalloid exposure. For example, several studies indicate impairment of the antioxidant system and decreases in GR activity and GSH levels when *Perna perna* mussels were exposed to zinc (Franco et al., 2006; Trevisan et al., 2014). Exposure to sublethal copper concentrations in *Mytilus galloprovincialis* also led to alterations (decreases) in total GSH content in both gills and the digestive gland, while sublethal mercury concentrations in the same species decreased tissue glutathione content when exposure was conducted with the organic mercury form (methylmercury), but did not significantly affect GSH content and metabolism when present in the inorganic form (Canesi et al., 1999), thus indicating that the chemical form of the contaminant is also of importance when evaluating metal and metalloid effects in these organisms. Other studies conducted with environmentally exposed mussels, such as the freshwater *Lasmigona costata* inhabiting a metal gradient, indicate that several biomarkers involving the SH metabolism, namely GSH, SH protein, total SH, GR and GST, were significantly correlated to gill metal concentrations (Machado et al., 2014), while alterations in GR and GPx were detected in the brown mussel *Perna perna* after exposure to 30 and 100 $\mu\text{mol L}^{-1}$ zinc (Franco et al., 2006).

Thus, it is a consensus that the glutathione metabolism plays an essential role in metal- and metalloid-induced responses in these organisms.

Several other enzymes are important in this regard, since they participate in the biotransformation process of xenobiotics, which occurs in two stages, Phase I and Phase II.

Phase I reactions are responsible for exposing or introducing functional chemical groups into xenobiotic molecules leading to an increase in their polarity, which can lead to the loss of toxic potential and their excretion, resulting in detoxification. At this stage reduction reactions catalyzed by the cytochrome P450 enzymes occur, as well as hydrolysis reactions, catalyzed by esterases and amylases, and oxidation reactions. Metabolites resulting from the metabolism of this first phase may subsequently undergo detoxifying during biotransformation in Phase II. During this second phase, conjugation reactions catalyzed by sulfotransferases, glucuronosyltransferases and GST occur, promoting the conjugation of a variety of toxic molecules with endogenous molecules. The conjugates, mostly soluble and often inactive, are then excreted.

However, the mechanism by which metals and metalloids alter the activity of these enzymes is still unknown. Thus, some hypotheses that attempt to explain this phenomenon have been postulated, as follows: (i) Metals and metalloids cause protein denaturation because they alter the ionic interactions existing between the amino acid side chains, causing changes in enzyme conformation, leading to loss of catalytic activity; (ii) Metals and metalloids may bind to an amino acid residue, for example, cysteines, containing the sulfhydryl group and displaying affinity for various metals and metalloids, close to the active site of the enzyme, making it impossible for the substrate to fit into the enzyme for the enzymatic catalysis process (Bainy et al., 2006; Goncalves et al., 2010; Romani et al., 2003; Sant'anna et al., 2011). It is important to emphasize that studies on the effect of metals and metalloids on enzyme activities are discrepant since certain parameters, such as exposure time and test concentrations, can stimulate, diminish or even alter the activity of this group of enzymes in exposed organisms (Bainy et al., 2006; Barata et al., 2004; Najimi et al., 1997; Richetti et al., 2011; Vioque-Fernández et al., 2007).

Several of these enzymatic biomarkers have been evaluated in mussels regarding metal exposure scenarios. In one study, the mussel species *Mytilus galloprovincialis* from the Saronikos Gulf of Greece was applied to monitor metal pollution in three contaminated sites and the results were compared to unpolluted site. Seasonal variations in superoxide dismutase (SOD) and catalase (CAT) activities were observed over three years in relation to concentrations of trace metals mussel gills and mantle, with SOD activity increasing at least 2-fold at the polluted sites, while CAT activity increased 2-3 times at the polluted sites, both compared to the control site (Vlahogianni et al., 2007). Another study investigated the toxic effects of zinc on antioxidant status and stress proteins in the gills of the brown mussel *Perna perna*, and indicated significant induction of CAT activities (Franco et al., 2006).

However, discrepant results in the literature are frequent regarding metal-induced alterations in these organisms. For example, in a study that conducted both a transplantation experiment of these organisms to a contaminated site and laboratory-exposure study to copper with *Mytilus galloprovincialis* polluted organisms (native, transplanted and Cu-exposed) showed significantly lower levels of glutathione and higher activities of glyoxalases (which detoxify reactive α -ketoaldehydes formed in cellular oxidative processes). However, native mussels from both the polluted and control populations exhibited similar GR, GPx, catalase, SOD and alkaline phosphatase activities, whereas, in both transplanted and Cu-exposed mussels, these enzymes showed significant variations. The authors postulate that these findings could suggest the occurrence of an adaptation or compensatory mechanism in chronically polluted organisms. In addition, they state that no clear results were obtained regarding GST, and that other esterases (arylesterases and cholinesterases) appeared not to be affected by metal pollution (Regoli and Principato, 1995).

MUSSEL RESPONSES TO NANOPARTICLE EXPOSURE

Nanotechnology applications have significantly expanded in the last decades, leading to the inevitable release of nanoparticles, mainly metal nanoparticles, into aquatic systems, resulting in growing environmental and human health concerns (Rocha et al., 2015b). Although very small, nanoparticles exhibit a high surface/volume ratio, providing them with a

high reactivity potential and unique physical and chemical properties that differ from conventional forms (Oberdörster et al., 2005).

In this context, research regarding these metal contaminants has increased in the last decades. Most studies expose mussels to both a metal nanoparticle and the dissolved form of the metal, in order to compare mechanisms of action and ecotoxicological effects. For example, *Mytilus galloprovincialis* specimens were exposed to $10 \mu\text{g L}^{-1}$ of Ag nanoparticles (Ag NPs) and ionic silver (Ag^+) for 15 days. Results indicate that both Ag forms, the NPs and ionic form, accumulated in both gills and digestive glands of the organisms. Regarding antioxidant enzymes, activities of superoxide dismutase, catalase and glutathione peroxidase were activated by both Ag NPs and Ag^+ , and displayed different antioxidant patterns in both gills and digestive glands. Moreover, metallothionein was induced in gills, directly related to Ag accumulation, while in the digestive glands only a small fraction of Ag seems to be associated with this protein. Thus, the authors indicate that Ag NPs and Ag^+ cause oxidative stress with distinct modes of action and it is not clear if for Ag NPs the observed effects are due to the free Ag^+ ions associated with the nanoparticle effect (Gomes et al., 2014).

In another study conducted with the same species, *Mytilus galloprovincialis* specimens were exposed to $10 \mu\text{g Cu} \cdot \text{L}^{-1}$ copper nanoparticles (CuO NPs) and Cu^{2+} in gills for 15 days. Results indicate that mussels accumulated copper in gills and responded differently to both copper forms, suggesting distinct modes of action. The CuO NPs induced oxidative stress by overwhelming the antioxidant defense system in gills, while Cu^{2+} exposure led to either unchanged or increased enzymatic activities. MT induction was also observed during both types of exposure, while neurotoxic effects reflected as AChE inhibition were only detected at the end of the exposure period for both copper forms (Gomes et al., 2011).

Tissue-specific responses related to alterations in the antioxidant defense system induced by CdTe quantum dots, in comparison with its dissolved counterpart, using the marine mussel *Mytilus galloprovincialis* have also been conducted. Results indicate that both Cd forms altered mussel antioxidant responses with distinct modes of action, tissue- and time-dependent differences in the biochemical responses to each Cd form, wherein QDs were more pro-oxidant when compared to dissolved Cd. Regarding tissue, the gills were observed as being the main tissue affected by QDs, with effects related to the increase of SOD, GST and GPx activities, while dissolved Cd was associated to increases in CAT activity, Cd accumulation and exposure time. The authors report that the digestive gland was the main tissue for accumulation of both Cd forms, but changes in antioxidant enzyme activities were noted as being lower than in gills. The authors conducted a multivariate analysis, that revealed that the observed antioxidant patterns are tissue dependent, indicating nano-specific effects possibly associated to oxidative stress and changes in redox homeostasis (Rocha et al., 2015a).

Another study on *Mytilus galloprovincialis* evaluated short-term effects on antioxidant enzyme activities and long-term genotoxic and carcinogenic potential of CuO NPs (NPs) in comparison to bulk CuO and ionic copper after 21 days exposure to $10 \mu\text{g Cu L}^{-1}$. After exposure, mussels were kept for up to 122 days in clean water. Results indicate that Cu accumulation depended on the form of the metal and on the exposure time, and that the three Cu forms produced different effects on antioxidant enzyme activities in digestive glands, overall increasing antioxidant activities. In addition, the authors report that CuO NPs significantly induced both catalase and superoxide dismutase activities, with fewer effects observed in gills (Ruiz et al., 2015).

However, nanoparticle studies have mostly been conducted on seawater species, with *Mytilus* genus as the main investigated taxa used as a model system (Rocha et al., 2015b). Thus, scarce literature is available on other species, indicating the need for further research in this regard in order to increase knowledge on the ecotoxicological effects of these emerging contaminants.

Some of the few examples found in the literature conducted with other species include a recent study on the toxicological perturbations resulting from zinc oxide nanoparticle exposure in the *Coelatura aegyptiaca* mussel, where the organisms were exposed to ZnO NPs (2, 10 and 50 mg L⁻¹) for 6 consecutive days. Exposure at 10 and 50 mg L⁻¹ induced a significant increase in malondialdehyde, superoxide dismutase and nitric oxide, with a concomitant decrease in reduced glutathione, glutathione-S-transferase and catalase levels in the haemolymph, digestive glands and gills of the treated mussels, indicating significant oxidative stress mechanisms of action (Fahmy and Sayed, 2017).

Sublethal effects of nanoparticle exposure in the freshwater mussel *Elliptio complanata* have also been evaluated. On study investigated the effects of CdTe quantum (1.6–8 mg L⁻¹) dot exposure in this species, while another, by the same research group, investigated the effects of increasing concentrations of 20-nm and 80-nm silver nanoparticles, as well as dissolved Ag⁺, for 48 h at 15°C. The former observed significant effects on hemocyte immuno competence (phagocytic activity, viability and cell lysis potential), as well as oxidative stress in gills and digestive glands, while a significant decrease in the number of DNA strand breaks was also observed at 4 and 8 mg L⁻¹, indicating inhibition of the DNA repair activity (Gagné et al., 2008). The latter observed that the response pattern of 80 nm nAg was more closely related to ionic Ag⁺ than 20 nm Ag, suggesting higher release of dissolved Ag from the 80 nm nAg. The authors, however, also report that all forms of Ag increased MT and LPO levels, suggesting that the presence of ionic Ag⁺ leads to oxidative stress. The nanoparticles also induced alterations in other proteins, such as ubiquitin, actinomyosin-ATPase, MT, and DNA strand breaks in the digestive gland in a manner different from Ag⁺, while LPO was closely associated with DNA strand breaks in the digestive gland and was not entirely explained by induction of MT, suggesting another type of toxic interaction. It was concluded that the presence of nAg not only increases the toxic loadings of released Ag ions but also generates other and perhaps cumulative effects of nanoparticle-induced toxicity related to size and surface properties (Gagné et al., 2013).

Overall, mussels display significant oxidative stress effects after nanoparticle exposure, and it seems that metals in the nanoparticle form show different mechanisms of action than those in free form, thus creating increased concerns regarding the effects of these emerging contaminants in the aquatic environment.

NECESSARY CONSIDERATIONS WHEN APPLYING MUSSELS AS BIOINDICATORS FOR METAL AND METALLOID EXPOSURE IN AQUATIC ECOSYSTEMS

Seasonal metal accumulation variations may be due to several abiotic factors. For example, increased precipitation in the summer may be responsible for pollutant dilution of pollutants and decreased metal concentrations in the water and, consequently, in mussels,

while differences in water temperature between summer and winter, which may affect mussel physiology and cause changes in metal concentrations in certain tissues (Szefer et al., 2004). In this regard, several factors have been postulated as the cause of the seasonal variations observed for biomarkers in mussels (Petes et al., 2008), including hyperthermia, hyposmotic stress, temperature and dissolved oxygen (Gourgou et al., 2010; Hamer et al., 2008; Jarque et al., 2014), as well as reproductive events, food availability and water temperature, among other factors (Amiard and Berthet, 1996; Mubiana et al., 2005; Wang and Dei, 1999).

In this context, significant seasonal variations have been reported for several antioxidant enzymes in mussel species, and conflicting results have ensued. For example, a study on the green-lipped mussel *Perna viridis* from Goa indicated that, although the oxidative stress status of gills and digestive gland of *P. viridis* expressed in terms of LPX and H₂O₂ were lowest in February, their levels were maximal in gills and digestive gland during May and November, respectively. On the other hand, SOD and GPX activities were low in August, and CAT and GR activities were low in February. GST activity in gills although remained high in February, while elevated values in the digestive gland were recorded in August and November (Verlecar et al., 2008). In another study, *Mytilus galloprovincialis* from the Gulf of Greece displayed seasonal variations in superoxide dismutase (SOD) and catalase (CAT) activities, as well as lipid peroxidation (LP). SOD activity displayed higher activity in spring, whereas CAT activity was highest activity in winter and spring. LP concentration was twice higher at the polluted sites, following the same seasonal pattern. However, trace metal showed only moderate variations along the months, with a winter maximum followed by a summer pre-spawning minimum (Vlahogianni et al., 2007).

Reproductive efforts, in particular, are known to lead to increases in metabolic activity, ROS and, consequently oxidative stress, as a result of reduced energy available for antioxidant defenses (Petes et al., 2008). Therefore, sampling should be avoided during the reproductive period, which is well documented for several commercial species (Mourgau et al., 2002).

In addition, mussel development stage may also be a confounding factor. For example, when comparing adult and juvenile *Mytilus edulis* after cadmium exposure for 20 days, juveniles expressed increased GSTpi expression compared to the adults, revealing variations in the expression of this GST isoform among control and Cd²⁺-exposed mussels of different ages (Ciocan and Rotchell, 2004).

In view of these factors, environmental monitoring studies should take care to conduct sampling efforts under standardized conditions (as much as possible), in order to avoid misinterpretation of biomarker results.

MUSSELS AND PUBLIC HEALTH

Bivalve shellfish culture and production for commercial purposes has been noted as a substantial contribution to the economic development of many countries (Santos et al., 2017).

However, the quality of mussels as food is closely related to the sanitary conditions of the marine environment where these bivalves are found (Oliveira et al., 2016), and public health risks associated with metal concentrations in these organisms have been increasingly reported for several species and geographical areas (Jović and Stanković, 2014). For example, in a

study conducted with *Mytilus galloprovincialis* mussels sampled along the marine coast of Boka Kotorska Bay, Montenegro, in the Adriatic sea, Cd, Co and Pb levels were recognized as limiting factors for mussel consumption by humans for some Adriatic areas in relation to the provisional tolerable weekly intake prescribed by the Joint FAO/WHO Expert Committee on Food Additives (JECFA), and the target hazard quotient (*THQ*) for average and high level mussels consumers in order to evaluate possible alert regarding adverse health effects that may be caused by trace metals individually (Jović and Stanković, 2014). A study conducted on *Perna perna* mussels in southern Brazil compared metal concentrations from 3 contaminated areas from the contaminated Guanabara Bay to a reference site, Ilha Grande Bay, and concluded that mussels from all sampling sites were improper for human consumption due to metal contamination (As, Se, Zn, Pb) according to both Brazilian and international standards, including Ilha Grande Bay, which was previously considered a reference site (Lavradas et al., 2016). Another study indicated that the invasive Indo-Pacific green mussel, *Perna viridis* (Linnaeus, 1758) in Jamaica accumulates significantly high levels of Cr and Cd, and that risks to public health through consumption of these mussels from Kingston Harbour are significant, exceeding the European Standards and Guidelines for Trace Metals in fish and shellfish. The authors suggest that depuration of the mussels prior to consumption should be carried out (Buddo et al., 2012).

The presence of metals in seafood depends on several factors including geographic location, species, size, feeding patterns and metal concentrations in the environment, which, in turn, are affected by many abiotic factors, such as solubility, temperature, salinity, dissolved oxygen and pH, among others (Stankovic and Jovic, 2012). Thus, it is clear that biomonitoring applying mussels as bioindicators is vital and directly linked to risk assessments regarding human population health, since these animals are a staple diet for many coastal populations, and, in recent years, have become commercially important seafood species worldwide (Stankovic and Jovic, 2012).

It is very important to note that many reports in the literature indicate no risk to human consumers due to low metal and metalloid levels in the digestive gland or gills of certain mussel species. However, these organisms are almost always ingested whole, so levels in this tissue only cannot be used to indicate public health risks, since total levels would be those present in muscle tissue, digestive gland and gills, summed. Thus, care should be taken in this regard when calculating possible public health risks.

CONCLUSION

Mussels are one of the most important bioindicator species applied to date to investigate the effects of metals and metalloids in the environment. Biomarker responses, such as protein and enzymatic alterations, to metal and metalloid exposure are routinely evaluated in several marine and freshwater species, although research on emerging contaminants, such as metal nanoparticles, is still recent. Public health risks associated with metal concentrations in these organisms have been increasingly reported for several species and geographical areas, since metal contamination in aquatic ecosystems has increased in the last decades, and thus, environmental monitoring efforts applying these organisms is paramount to attempt public decision-making processes regarding environmental metal and metalloid contamination.

Chapter 547

CLIMATE CHANGE AND ITS POTENTIAL RISKS TOWARDS PUBLIC HEALTH

***Devojit Kumar Sarma^{*}, Manoj Kumar, Swasti Shubham,
Anil Prakash and Rajnarayan R. Tiwari***

ICMR-National Institute for Research in Environmental Health Bhopal,
Madhya Pradesh, India

ABSTRACT

Climate change refers to any change in climate over time, whether due to natural variability or as a result of human activity. However, the present scenario of climate change is mostly due to anthropogenic or human-made. Humans are integrally related to the climatic changes directly or indirectly both in cause and impacts. The current trend in climate change has both short term as well as long term effects among which most of them are negative effects on humanity. This chapter deals with the potential impacts of present climate change on different aspects of human health and their future repercussion, discusses gaps for further research to generate shreds of evidence that will help in framing effective and proper adaptation and mitigation strategies to avoid the black shadow of climate change.

Keywords: climate change, global warming, disease, health

INTRODUCTION

Human history is intricately related to climatic disparity and change. Nature has already experienced nearly two full glacial and inter-glacial cycles in the history of the earth among which the last glacial period favored the global geographical expansion, massive population increase and worldwide ecological domination of *Homo sapiens* which was furthermore

^{*} Corresponding Author's Email: dkbiotek@gmail.com.

extended during the last glacial-interglacial transition. During the past 25,000 years, the Earth system has undergone a series of dramatic transitions. The most recent glacial period peaked 21,500 years ago during the Last Glacial Maximum (LGM) where there was an expansion of ice sheet cover over the globe resulting the global sea level down to 125 meters (410 feet) below today's level with surface temperatures about 5°C (9°F) cooler than today.

Earth's atmosphere is made up of oxygen, a large amount of nitrogen and a small percentage of greenhouse gases (GHGs), such as carbon dioxide (CO₂) and methane. In the 1820s, French mathematician and physicist Joseph Fourier proposed that the green house gases act like a blanket around the Earth and they trap heat from the sun and make life on Earth possible. However, it took nearly 40 years when Irish scientist John Tyndall, in 1860, demonstrated exactly what kinds of gases were most likely to play a role in absorbing sunlight. In 1895, Swedish chemist Svante Arrhenius showed that if CO₂ levels were halved, global temperatures could decrease by about 5°C, explaining the effect of lower global CO₂ level due to decreased volcanic activity on past ice ages. He also suggested that if CO₂ levels were doubled, global temperatures would increase by the same amount, i.e., 5°C. British engineer Guy Stewart Callendar, in 1930s, noted that due to the ongoing "Industrial Revolution" the United States and North Atlantic region had warmed significantly. Callendar's calculations suggested that a doubling of CO₂ in Earth's atmosphere could warm Earth by 2 degrees C (3.6 degrees F) and he put forwarded the theory that warming of the planet due to greenhouse-effect was underway. However, during 1940-1970, due to a postwar boom in aerosol pollutants which reflected back sunlight away from earth, a cooling effect was observed. This was further explained scientifically by Broecker in 1975 [1], where he supported the observation made by Callender and stated that

"This cooling has, over the last three decades, more than compensated for the warming effect produced by the CO₂ released into the atmosphere as a by-product of chemical fuel combustion. By analogy with similar events in the past, the present natural cooling will, however, bottom out during the next decade or so. Once this happens, the CO₂ effect will tend to become a significant factor and by the first decade of the next century we may experience global temperatures warmer than any in the last 1000 years."

Broecker was the first to introduce the term "Global Warming." This led to increased scientific interest and research on this front. Hansen et al. 1988 [2], using a three dimensional climate model, the Goddard Institute for Space Studies (GISS) model II with 8° X 10° horizontal resolution, showed that the global warming within the next several years is predicted to reach and maintain a level of at least three standard deviations (3SD) above the climatic conditions of the 1950s. Understanding these changing scenarios and related consequences, the United Nations established the Intergovernmental Panel on Climate Change (IPCC) in 1989 to provide a scientific view of climate change and its political and economic impacts. According to IPCC, climate change refers to a change in the state of the climate that can be identified (e.g., using statistical tests) by changes in the mean and/or the variability of its properties and that persists for an extended period, typically decades or longer. It refers to any change in climate over time, whether due to natural variability or as a result of human activity [3]. According to the IPCC published landmark report in 2007, there is unequivocal evidence of global warming. Increase in green house gases is attributing towards most of the warming within the past 50 years affecting the physical and biological systems on all continents and oceans [4]. The next few decades are likely to witness more warming. The effect of emissions in the long term is becoming more evident [5].

CLIMATE VS. WEATHER

The concepts of climate and weather are often confused. *Weather* is the state of the atmosphere at any given time and place. Weather patterns vary greatly from year to year and from region to region. Familiar aspects of weather include temperature, precipitation, clouds, and wind that people experience throughout the course of a day. Severe weather conditions include hurricanes, tornadoes, blizzards, and droughts. *Climate* is the average weather conditions that persist over multiple decades or longer. While the weather can change in minutes or hours, identifying a change in climate has required observations over a time period of decades to centuries or longer [6]. According to NOAA, climate is the average of weather over at least a 30 -year period. Climate change encompasses both increases and decreases in temperature as well as shifts in precipitation, changing risks of certain types of severe weather events, and changes to other features of the climate system.

EVIDENCE OF CLIMATE CHANGE

A change in earth's climate is becoming evident with the rising temperatures, shifting rainfall patterns and more extreme climatic events such as heavy rainstorms, heat waves and cold waves. There are ample evidence that these observed changes are linked to the rising levels of carbon dioxide and other greenhouse gases in our atmosphere, caused by human activities. The United States Environmental Protection Agency (EPA) published "*Climate Change Indicators in the United States*," in 2016. This report presents 37 indicators, each describing trends related to the causes and effects of climate change [6]. The evidence includes:

- Increase in global average surface temperature by 2 degrees Fahrenheit ($\sim 1^{\circ}\text{C}$) in the last century (Figure 1). Global average surface temperature has risen at an average rate of 0.15°F (0.09°C) per decade since 1901.
- On average, total annual precipitation has increased over land areas worldwide. Since 1901, global precipitation has increased at an average rate of 0.08 inches per decade. (Figure 2) [8].
- Sea surface temperature increased during the 20th century and continues to rise. From 1901 through 2015, the temperature rose at an average rate of 0.13°F per decade. Sea surface temperature has been consistently higher during the past three decades than at any other time since reliable observations began in 1880.
- Global average sea level rose throughout the 20th century, and the rate of change has accelerated in recent years. When averaged over all of the world's oceans, absolute sea level has risen at an average rate of 0.06 inches per year from 1880 to 2013. Since 1993, however, average sea level has risen at a rate of 0.11 to 0.14 inches per year—roughly twice as fast as the long-term trend.
- Measurements made over the last few decades have demonstrated that ocean carbon dioxide levels have risen in response to increased carbon dioxide in the atmosphere, leading to an increase in acidity (that is, a decrease in pH).

Figure 1. Average annual global temperatures from 1880 to 2018 compared to the long-term average (1901-2000). The zero line represents the long-term average temperature for the whole planet; blue and red bars show the difference above or below average for each year (adapted from [7]).

Figure 2. Anomalies in total annual amount of global precipitation change for period 1901-2015. This graph uses the 1901–2000 average as a baseline for depicting change. (Adapted from [8]).

- Reduction of ice caps. Arctic sea ice now starts melting 11 days earlier and it starts refreezing 26 days later than it used to, on average. Overall, the Earth has lost sea ice at an average rate of 13,500 square miles per year since 1979. This decrease affects the Earth’s energy balance.

- On average, glaciers worldwide have been losing mass since at least the 1970s, which in turn has contributed to observed changes in sea level. A longer measurement record from a smaller number of glaciers suggests that they have been shrinking since the 1940s. The rate at which glaciers are losing mass appears to have accelerated over roughly the last decade.

A number of biological changes have also been observed. These include shifts in the ranges of some plant and animal species, earlier timing of spring events such as leaf-unfolding, bird migration and egg-laying for some species. Together these indicators provide clear evidence that the climate is changing.

CLIMATE CHANGE PROJECTIONS

Continued emissions of greenhouse gases will lead to further changes in the prevailing climate over any space. Future changes are expected to include a warmer atmosphere, a warmer and more acidic ocean, higher sea levels, and larger changes in precipitation patterns. The extent of future climate change depends on what we do now to reduce greenhouse gas emissions. The more we emit the larger future changes will be. Projecting future changes to the Earth's climate vary widely based on different climate modeling approaches generating different types of datasets.

Global climate models or general circulation model (GCMs) are the most widely used method to understand what the climate may be like in the future as a result of emissions of greenhouse gases (global warming). They are run on supercomputers that attempt to simulate the complex atmospheric and oceanic processes that determine the climate conditions. Because they work at a global scale, the resolution of GCM results is typically quite coarse (usually about 300 X 300 KM resolution). These projections are helpful for decision makers and resource managers to formulate adaptation policies in response to climate change impacts. Although GCMs provide adequate simulations of atmospheric general circulation at the continental scale, they do not capture the details required for regional and national assessments. Therefore, reliable climate change information is required at finer spatial scales. Regional climate models (RCMs) are applied to smaller spatial areas to produce results with greater local detail (usually about 25 X 50 KM resolution). However, RCMs still rely on GCMs for input data and therefore are not necessarily more reliable or more accurate [9]. GCMs and RCMs are run under different scenarios of future greenhouse gas emissions – from a best-case scenario (if extensive action is taken to reduce emissions levels) to the worst-case (if emissions keep rising with no action taken to reduce them), whereby they generate a number of possible climate futures (projections).

The first Intergovernmental Panel on Climate Change Assessment Report (IPCC FAR) in 1990 discussed three types of scenarios: equilibrium scenarios, in which CO₂ concentration was fixed; transient scenarios, in which CO₂ concentration increased by a fixed percentage each year over the duration of the scenario; and four brand-new Scientific Assessment (SA90) emission scenarios based on World Bank population projections [10]. The standard sets of time-dependent scenarios used by the climate modeling community as input to global climate model simulations provide the basis for the majority of the future projections presented in

IPCC assessment reports and U.S. National Climate Assessments (NCAs). Developed by the integrated assessment modeling community, these sets of standard scenarios have become more comprehensive with each new generation, as the original SA90 scenarios [11] were replaced by the IS92 emission scenarios of the 1990s [12], which were in turn succeeded by the Special Report on Emissions Scenarios in 2000 (SRES) [13] and by the Representative Concentration Pathways (RCPs) in 2010 [14]. Box 1 explains about the different scenarios under SRES and RCP projection scenarios. Based on the SRES and RCP projection scenarios, the future climatic projections for CO₂ emission, concentration and temperature for 2100 is shown in Figure 3 [16].

Box 1.

(A). SRES scenarios

SRES contains 40 scenarios that fall into four qualitative storylines [13]: A1, A2, B1 and B2.

The A1 storyline describes a future world of very rapid economic growth, global population that peaks in the mid twenty-first century and declines thereafter. The A1 family develops into three groups that describe alternative directions of technological change in the energy system. These three: A1FI is fossil intensive (highest), A1T is non-fossil energy sources (mid), and A1B is a balance across all sources (lowest).

The A2 storyline describes a very heterogeneous world. The global population increases continuously and the economic development is primarily regionally oriented and per capita economic growth is more fragmented and slower than in other families.

The B1 storyline describes a convergent world with the same global population that peaks in the mid twenty-first century and declines thereafter, as in the A1 family, but with rapid changes in economic structures toward a service and information economy, with a reduction in material intensity, and the introduction of clean and resource-efficient technologies.

The B2 storyline describes a world in which the emphasis is on local solutions to economic, social, and environmental sustainability. The global population increase is at a lower rate than A2 family, intermediate levels of economic development, and less rapid and more diverse technological change than in the B1 and A1 families. The scenario is oriented towards environmental protection but it focuses on local and regional levels.

(B). RCP scenarios:

Four pathways have been selected for climate modeling and research, which describe different climate futures, all of which are considered possible depending on how much greenhouse gases are emitted in the years to come. The four RCPs, namely RCP2.6, RCP4.5, RCP6, and RCP8.5, are labeled after a possible range of *radiative forcing* values in the year 2100 (2.6, 4.5, 6.0, and 8.5 W/m², respectively) [15].

The RCPs are consistent with a wide range of possible changes in future anthropogenic (i.e., human) *greenhouse gas* (GHG) emissions, and aim to represent their atmospheric concentrations [4].

RCP 2.6 Peak in radiative forcing at ~ 3 W/m² before 2100 and decline

Emissions in RCP 4.5 Stabilization without overshoot pathway to 4.5 W/m² at stabilization after 2100

In RCP 6, Stabilization without overshoot pathway to 6 W/m² at stabilization after 2100

In RCP 8.5, Rising radiative forcing pathway leading to 8.5 W/m² in 2100.

CLIMATE CHANGE IN INDIA

Although India accounts for only 4.5 percent of the world's greenhouse gases, based on the best available pieces of evidence and computer simulation, it is one of the few countries which is going to be influenced by climate change in its extremity in near future because of

its diverse terrain, geography, diverse population characteristics and extremely high dependence on fossil fuels [17-18]. As the natural resources are rapidly exhausting along with the destruction of natural environment mostly due to increased population, urbanization, industrialization and economic growth, the country is expected to experience a serious impact of climate change in many areas such as agriculture, water resources, food safety, cities, coastal ecosystems and on health [19].

Figure 3. Future CO₂ emission, concentration and temperature projections based on SRES (left) and RCP (right) pathways [adapted from 16].

The latest high-resolution climate change scenarios and projections for India are based on a regional climate modeling system known as PRECIS (Providing Regional Climates for Impact Studies), which was developed by the Hadley Centre (the research centre of the national weather service in the United Kingdom) and applied in India using scenarios developed by the Intergovernmental Panel on Climate Change. The latest projections for India are [20, 21, 22]:

- Annual mean surface temperature will rise by the end of the century, by from 2.5°C to 5°C, with warming more pronounced in the northern parts of India (Figure 4 & 5)
- More than 20% (15-24%) rise in summer monsoon rainfall is projected over all states except Punjab, Rajasthan and Tamil Nadu
- The range of maximum temperatures in any one season is predicted to vary more widely (for example, from between 27°C and 44°C to between 26°C and 45°C); variations in minimum temperature are expected to increase in the same way
- Rainfall is expected to increase substantially, particularly over the west coast of India and west-central India.

Time series of surface air temperature change (°C) (Max. Temp. anomalies, relative to the present day). Projected annual mean surface temperature from multimodel average CMIP5 data for the years 1860–2100 relative to the base period 1901–1960. Adapted from [22].

Figure 4. Projected surface temperature for India over the period of 1860-2100.

Figure 5. Geographical distribution of surface temperature trends (K/decade) at the 95% confidence level from RCP2.6 and RCP 8.5 for different periods over India for the 21st century. (Adapted from [22]).

IMPACTS OF CLIMATE CHANGE

The impacts of human-caused climate change are already being seen, from polar regions to rising temperature, to communities around the world and to the local environments. Consequences of climate change will affect the biosphere on many levels, from coral bleaching to dying forests, to species extinction. Most of the impacts of Climate change are negative and will be hitting the sectors such as water resources, energy supply and use, transportation, agriculture, ecosystems (forestry & biodiversity), human health, economy and society [23]. Hitz and Smith (2004) [24] found that the relationships between global mean temperature (GMT) and impacts are not consistent across sectors. Some of the sectors such as coastal resources, biodiversity, and possibly marine ecosystem productivity will exhibit increasing adverse impacts with increasing global mean temperature. . Other sectors are characterized by a parabolic relationship between temperature and impacts (benefits at lower global mean temperature increases, damages at higher global mean temperature increases), in particular, agriculture, terrestrial ecosystem productivity, and possibly forestry. The relationship between global impacts and increase in global mean temperature for water, health, energy, and aggregate impacts appears to be uncertain and a matter of thorough research. Overall, it appears likely that there are increasing adverse impacts at higher increases in GMT.

CLIMATE CHANGE AND HUMAN HEALTH

Global climate change has become one of the most visible environmental concerns over the 21st century. Environmental consequences of climate change, such as extreme heat waves, rising sea levels, changes in precipitation resulting in flooding and droughts, intense hurricanes, and degraded air quality, affect directly and indirectly the physical, social, and psychological health of humans (Figure 6). For instance, changes in precipitation are creating changes in the availability and quantity of water, as well as resulting in extreme weather events such as intense hurricanes and flooding. Climate change can be a driver of disease migration, and exacerbate health effects resulting from the release of toxic air pollutants in vulnerable populations such as children, the elderly, and those with asthma or cardiovascular disease.

In September 2015, 193 world leaders committed to achieve 17 sustainable development goals (SDGs) and 169 targets to end extreme poverty, fight inequality and injustice and protect our planet by 2030. Climate change and health featured prominently in this “Agenda 2030 for Sustainable Development” as a new set of goals [25].

However, to date, most climate change research has focused on environmental effects, not on health effects. Evidence-based information generation and understanding of the often indirect, long term and complex interactions of climate change on human health is a top priority research task to be conducted. In 2000, WHO estimated 1,66,000 deaths and about 5.5 million disability-adjusted life years (DALYs) only because of four diseases (cardiovascular disease, malnutrition, diarrhea, and malaria) as well as floods, that were attributable to climate change [26]. To date, the majority of analyses on climate change and health have focused on diseases that predominantly affect people in the developing world, and

therefore, are perceived as less relevant to more developed countries. However, as the recent pandemic of H1N1 virus has shown us, diseases do not respect international boundaries. Climate change can be a driver for disease migration, but even so, such diseases do not represent the broadest range of possible, or even likely, human health effects of climate change, nor do they reflect the likely co-benefits of mitigation and adaptation to climate change, some of which may have their greatest impact in the developed world. There is a substantial gap in our understanding of the complex relationship among climate change, the environment and human health globally [27] which needs to be bridged.

Climate change directly affects five components of the environment: water, air, weather, oceans, and ecosystems. Changes in rainfall pattern, temperature fluctuations, and melting of ice glaciers are already happening and will create changes in the availability and quality of water across the globe over the next 30 years [28]. The air quality is modulated by heat, humidity, the degree of ultraviolet (UV) radiation, and many other factors and changes in any of these can directly reduce air quality, particularly in urban areas, by increasing air concentrations and human exposures to a variety of toxic air pollutants. In many areas of the country, climate change and resulting weather events such as drought and wildfires will reduce general air quality resulting increases in asthma, cardiovascular disease, and other respiratory ailments. Extreme heat also directly increases the risk of injury, illness, and death, as well as indirectly by contributing to illnesses such as those associated with mental health and stress in developing countries [29]. The warming of ocean waters contributes to increases in incidence and severity of toxic algal blooms, alterations in aquatic and estuarine food webs and seafood quality and availability, and effects on sentinel aquatic species. Changes in plant habitat can result in reduced availability of grazing lands for livestock [30]. Global warming is also causing shifts in the ranges of disease vectors that require specific environments to thrive (for example, Lyme disease and dengue vectors) [31] and increasing the threat and incidence in humans of waterborne, vectorborne and zoonotic (those transferred from animals to humans) diseases (Table 1).

Figure 6. Impact of climate change on human health.

The Interagency Working Group on Climate Change and Health (IWGCCH) in its white paper has identified the following human health categories to be affected by climate change demanding research needs to identify mitigation and adaptation [32].

Asthma, Respiratory Allergies and Airway Diseases

Globally approximately 235 million people suffer from asthma and among these India has an estimated 15-20 million asthmatics with a prevalence of 10-15% in children below 11 years old [33]. In recent decades, the world has seen a sharp rise in prevalence as well as severity of respiratory diseases mostly in low and middle-income countries with environmental factors such as outdoor and indoor air pollution like tobacco smoke as a major risk factor [34] and extended by climate change [35]. In many low and middle-income countries including rural areas of India, people rely on solid fuel (wood, cow dung or crop residues) that they burn in simple stoves or open fires for domestic energy [36].

Table 1. Examples of how diverse environmental changes affect the occurrence of various infectious diseases in humans

Environmental changes	Example diseases	Pathway of effect
Dams, canals, irrigation	Schistosomiasis	☞ Snail host habitat, human contact
	Malaria	☞ Breeding sites for mosquitoes
	Helminthiasis	☞ Larval contact due to moist soil
	River blindness	☞ Blackfly breeding, ☞ disease
Agricultural intensification	Malaria	Crop insecticides and ☞ vector resistance, ☞ disease
	Venezuelan haemorrhagic fever	☞ Rodent abundance, contact
Urbanization, urban crowding	Cholera	☞ Sanitation, hygiene; ☞ water contamination
	Dengue	Water-collecting trash, ☞ Breeding sites for mosquitoes
	Cutaneous leishmaniasis	☞ Proximity, Sandfly vectors
Deforestation and new habitation	Malaria	☞ Breeding sites and vectors, immigration of susceptible people
	Oropouche	☞ Contact, breeding of vectors
	Visceral leishmaniasis	☞ Contact with sandfly vectors
	Dengue	☞ Contact, breeding of vectors
Reforestation	Lyme disease	☞ Tick hosts, outdoor exposure
	Kyasunur Forest Disease	☞ Tick hosts, outdoor exposure
Ocean warming	Red tide	☞ Toxic algal blooms
Elevated precipitation	Rift valley fever	☞ Pools for mosquito breeding
	Hantavirus pulmonary syndrome	☞ Rodent food, habitat, abundance

Many respiratory allergic diseases are seasonal with climate-sensitive components; climate change may increase the incidence and exacerbation of such allergic diseases. While

some risk for respiratory disease can be clearly linked to climate change, for many others the risk attributable to climate change is unclear. In addition to impacts on asthma and other allergic diseases, climate change has the potential to impact airway diseases by increasing ground level ozone and possibly fine particle concentrations. Both ozone, indoor air pollutants (other than tobacco smoke) and $PM_{2.5}$ lead to several cardio-pulmonary disorders like breathing difficulty, worsening of asthma, bronchitis and emphysema, decreased lung function, cardiovascular events and even death. [37, 38, 39]. Cecchi et al. 2010 [40] projected that increasing effect of aeroallergens may imply a greater likelihood of the development of allergic respiratory disease in sensitized subjects and exacerbation of symptomatic patients. There is also a possibility that certain aeroallergens may become more allergenic as temperatures and CO_2 concentrations increase [41, 42, 43, 44]. Another respiratory disease such as “Thunderstorm related Asthma” is found to be linked with humidity, temperature, respirable particulate matter and bioaerosols which are highly influenced by climate change [45, 46]. Research studies found an association of fine particles with cardiovascular outcomes such as heart attacks, formation of deep vein blood clots, and increased mortality [43, 47-52]. These adverse health impacts intensify as temperatures rise [53]. The temperature-mortality relationship has been shown to be established for cardiovascular disease (CVD), followed by respiratory disease and total mortality in temperate countries. These relationships are supported by strong evidence for direct links between high and low temperatures and increased blood pressure, viscosity and heart rate for CVD [54] and broncho-constriction for pulmonary disease [55].

Figure 7. Projected ambient $PM_{2.5}$ exposure over the Indian landmass under both RCP4.5 and RCP8.5 scenarios. Shaded part represents the range (1–99%) in all-India averaged $PM_{2.5}$ across the 13 CMIP5 models. The black line represents the all-India averaged baseline (2001–2005) $PM_{2.5}$ exposure level. (Adapted from [59]).

India is at a higher risk with wide variation in temperature and higher level of air pollutants. However, very limited work has been carried out on this front in India [56]. An investigation on the effects of air pollution on respiratory disease showed that emergency department visits increased by approximately 20% because of high levels of pollutants in Delhi [57]. In another study based in Chennai, India, [58] concluded that short-term exposure

to particulate matter $\leq 10 \mu\text{m}$ in aerodynamic diameter (PM_{10}) resulted in an estimated risk ratio of 1.0044 (95% CI, 1.002–1.007) per a $10 \mu\text{g}/\text{m}^3$ increase in daily average concentrations. Recently, Choudhury et al. 2018 [59] modeled the ambient $\text{PM}_{2.5}$ exposure up to 2100 under the climate change scenario and concluded that ambient $\text{PM}_{2.5}$ exposure is expected to peak in 2030 under the RCP4.5 and in 2040 under the RCP8.5 scenario. Premature mortality burden is expected to be 2.4–4 and 28.5–38.8% higher under RCP8.5 scenario relative to the RCP4.5 scenario in 2031–2040 and 2091–2100, respectively (Figure 7).

Cancer

Cancer is the second leading cause of death globally after cardiovascular diseases [60]. In India, 8.3% (95% uncertainty interval [UI] 7.9–8.6) of the total deaths and 5.0% (4.6–5.5) of the total DALYs in India in 2016 were due to cancer [61]. Climate change has both indirect as well as direct effect on cancer. Due to climate change, ambient temperatures will rise which may increase the transfer of volatile and semi-volatile compounds from water and wastewater into the atmosphere resulting in distribution and exposure of contaminants to places more distant from the sources [62]. Climate change is also expected to increase heavy precipitation and flooding events, which may increase the chance of toxic contamination leaks from storage facilities or runoff into water from land containing toxic chemicals and heavy metals. Very little is known about how such events will affect people's exposure to these chemicals, some of which are known carcinogens, and its ultimate impact on incidence of cancer [63]. On the other hand, some cancer such as lung cancer and skin cancer has a direct connection to climate change. Smoking is considered as the main cause of lung cancer, but air pollution [64] including indoor air pollution and fine particulates [65–67] also contributes to the burden of lung cancers. Another direct effect of climate change is depletion of stratospheric ozone which will result in increased ultra-violet (UV) radiation exposure leading to increased risk of skin cancer [68–69]. Rising temperatures and diurnal temperature were found to be associated with increases in UV exposure due to climate change which may lead to an increase in the incidence of non-melanoma skin cancers [70–72].

Cardiovascular Disease and Stroke

Cardiovascular diseases (CVD) accounts for most of the deaths (~18million) due to non-communicable diseases globally [73]. In India too, mortality due to cardiovascular diseases and stroke made the highest contribution (28.1%) in 2016 increasing by ~34.3% in the last 25 years [74]. Long-term exposure to ambient particulate matter $\text{PM}_{2.5}$ has been considered as a potential risk factor to cardiovascular and respiratory diseases [75]. India is recognized as a hotspot for aerosol loading [76] where ambient $\text{PM}_{2.5}$ exposure was observed to increase rapidly over the past decade (2001–2010) [77]. The annual premature mortality burden from ambient $\text{PM}_{2.5}$ exposure in India is currently estimated to be ~1.0 million [78].

Weather conditions such as extreme heat and extreme cold are evident for several CVDs affecting the incidence of hospital admissions for chest pain, acute coronary syndrome,

stroke, and variations in cardiac dysrhythmias [79-82]. Similarly, stroke and CVD incidences are also found to be increased with increasing temperature specifically in both elderly and isolated individuals [83-84]. There are many indirect impacts of weather, weather variability and climate changes on CVDs. Weather and climate modifies the associations between air quality, especially ozone and particulate matters, and incidence and mortality of CVD., acute myocardial infarction and ischemic heart disease in most of the low and middle-income countries [85-90]. Under the climate change projections, it has been also observed that the increasing temperatures and number of hot day will increase cardiovascular diseases related mortality in Middle East and China including India in near future [91-93]. Although not prevalent in India, Chagas diseases, which is expected to rise due to climate change, will also increase manifestation of stroke and heart failure in South America [94].

Food-Borne Diseases and Nutrition

The potential effects of climate change on food-borne illness, nutrition, and food security are mostly indirect. However, there is a proven link between food security to climate change and it may affect food safety and the incidence of food-borne illness [95]. Extreme weather events, changes in temperature and precipitation patterns resulting in flood or drought can directly damage or destroy crops and thereby impacts food quality, food supplies, interrupt transport and distribution of food. Indirectly, this results to undernutrition or famine resulting from damage to agricultural crops and related trade, economic, and social instability. Food-borne illness results from ingesting food that is spoiled or contaminated with microbes, chemical residues such as pesticides, biotoxins, or other toxic substances.

It was estimated that food-borne diseases caused ~600 million illness including 420000 deaths, mostly in children, globally in 2010. Among the 31 global hazards causing food-borne illness, diarrhoeal diseases are the most common illness resulting from unsafe food accounting for 230000 deaths globally of which ~100000 are under the age of 5 years [96]. It was observed that increased temperature due to climate change impacts the rate of food-borne illness. Checkley et al. 2000 [97] recorded each degree Celsius rise in average ambient temperature increases the incidence of diarrhea in Lima, Peru (Figure 8). A similarly strong positive correlation was also observed between high temperature and *Salmonella* infections by Akil et al. 2014 [98]. Using modeling approaches such as regression analysis and neural network, they have found that an increase of 1°F was shown to result in four cases increase of *Salmonella* in Mississippi. Kim et al. 2015 [99] observed that different food-borne pathogens are affected differently by changes in climatic variables such as temperature and relative humidity. Eight pathogens commonly associated with food-borne diseases were identified and the effect of changes in temperature and relative humidity on each of them was investigated. Pathogenic *Escherichia coli* had the strongest correlation with temperature and relative humidity, followed by *Vibrio parahaemolyticus*, *Campylobacter jejuni*, *Salmonella* spp., and *Bacillus cereus*. On the other hand, Norovirus had a strong negative correlation with temperature and relative humidity, followed by *Clostridium perfringens* and *Staphylococcus aureus*.

Rising temperatures and impacts on other environmental parameters such as ocean acidification may also lead to more virulent strains of existing pathogens and changes in their distribution or the emergence of new pathogens [100].

Figure 8. Effect of increase of temperature on diarrhea incidence (adapted from [97]).

In India, the number of foodborne diseases is expected to rise from 100 million in 2011 to ~170 million in 2030 [101]. Therefore, it's a high time to put more emphasis on foodborne diseases research from the point of climate change to identify the mitigation approaches.

Heat-Related Morbidity and Mortality

Due to the anthropogenic climate change, the global mean temperature is increasing and is expected to be increasing far more regardless of the reducing greenhouse gas emissions. It is estimated that human activities have caused approximately 1.0°C rise of global warming above pre-industrial levels, with a *likely* range of 0.8°C to 1.2°C. Global warming is *likely* to reach 1.5°C between 2030 and 2052 if it continues to increase at the current rate [102] and is likely to increase between 1.8 and 4.0°C by 2100 [28]. Climate change is expected to raise overall temperature distribution and contribute to an increase in the frequency of extreme heat events, or heat waves in different parts of the globe [103] which is associated with a wide range of health illness and deaths by exacerbating preexisting chronic conditions such as various respiratory, cerebral, and cardiovascular diseases [104] as well as increasing risk for patients taking psychotropic drug treatment for mental disorders [105] due to the body's impaired ability to regulate temperature. Heat related morbidity and mortality can be due to either direct or indirect effects [104]. Direct effects include a spectrum of heat illness ranging

from heat exhaustion to heat stroke; the indirect effects occur when heat exposure stresses underlying physiological systems and results in other specific manifestations such as renal insufficiency, acute cerebrovascular disease, and exacerbations of pulmonary disease [106].

Among historic heat waves, some have been associated with large numbers of all-cause and cause-specific deaths, notably in France, Europe more broadly, Chicago and California [107-110]. During the 2003 heat wave in France, excess mortality in 13 French cities varied from 4% to 142%, with a majority of cities experiencing excess mortality in the 20–50% range [107, 26]. During the 2006 heat wave in California, there were an estimated 16,166 excess emergency department visits and 1,182 excess hospitalizations state-wide [109]. In 2010, Moscow and Western Russia experienced a heat wave with ambient temperatures exceeding 39°C, and a high number of deaths, though specific estimates of excess morbidity and mortality have not been done [111].

Table 2. Heatwave events in India (Adapted from [115-116])

Sl. No.	Year	No. of heat wave days	Place	Lives lost
1	1979	16	Orissa, Andhra Pradesh, Gangetic West Bengal, Uttar Pradesh, Bihar	365
2	1980	7	Uttar Pradesh, Maharashtra, Tamil Nadu, Andhra Pradesh	106
3	1981	7	Uttar Pradesh, Madhya Pradesh, Bihar	63
4	1982	4	Uttar Pradesh	11
5	1983	11	Bihar, Punjab, Uttar Pradesh, Maharashtra	185
6	1984	11	Punjab, Uttar Pradesh, Maharashtra	58
7	1985	5	Punjab, Bihar	141
8	1986	8	Andhra Pradesh, Punjab, Rajasthan, Himachal Pradesh, Bihar	155
9	1987	6	Orissa, Punjab, Haryana, Uttar Pradesh	90
10	1988	21	Rajasthan, Gujarat, Saurashtra & Kutch, Uttar Pradesh, Punjab	924
11	1989	15	Rajasthan, Madhya Pradesh, Maharashtra	43
12	1990	6	Rajasthan	
13	1991	10	Rajasthan, Madhya Pradesh, Maharashtra, Gujarat	250
14	1992	13	Rajasthan, Madhya Pradesh, Haryana, Bihar, Uttar Pradesh, Maharashtra	114
15	1993	13	Punjab, Haryana, Rajasthan, Uttar Pradesh	73
16	1994	25	Punjab, Haryana, Rajasthan, Uttar Pradesh, Madhya Pradesh, Maharashtra	234
17	1995	29	Haryana, Rajasthan, Punjab, Uttar Pradesh	410
18	1996	9	Rajasthan, Haryana, Uttar Pradesh	17
19	1998	27	Punjab, Rajasthan, Gujarat, Uttar Pradesh, Maharashtra, Orissa, Andhra Pradesh, South Tamil Nadu	1300
20	1999	14	north-west and central India	
21	2003		Andhra Pradesh	3000
22	2010		Ahmedabad	1300
23	2015		Andhra Pradesh, Telengana, Odisha, Uttar Pradesh, West Bengal, Gujarat, Madhya Pradesh, Delhi, Maharashtra, Rajasthan, Chattisgarh, Bihar, Karnataka	2500

In India, heat waves often lead to loss of human and animal life, while enhancing morbidity and discomfort (Table 2). Official records of the India Meteorological Department (IMD) indicate that there have been approximately 223 heatwave incidents between 1978 and 1999, causing more than 5,300 deaths [112]. Premature mortality in India is experienced more in rural populations, particularly among elderly and outdoor workers. Omid et al. 2017 [113]

observed that Mean temperatures across India have risen by more than 0.5°C over the period of 1960-2009, with statistically significant increases in heat waves. Similarly, Concurrent day and nighttime heatwaves can exacerbate human discomfort causing high morbidity and mortality. Mukherjee and Mishra, 2018 [114] reported an increase 12-fold of the current level by the end of 21st century and 4-fold by the mid 21st century under the high emission pathway of RCP 8.5 Concurrent day and nighttime heatwaves. India has had several historic heat waves. Most notably, in May 1998, India experienced a severe heat wave over a 2-week period, which was considered to be the worst in the previous 50 years [115]. The following year, a similar record-breaking event occurred in 1999 in north-west and central India. According to Kalsi et al. 2001 [116], during the summer of 1999, India experienced unprecedented heat in April, with maximum temperatures of 40°C or above for more than 14 days. Another heat wave in 2003 caused more than 3,000 deaths in Andhra Pradesh. Under a 2°C warming scenario, it was observed that the frequency of severe heat waves in India will increase 30-fold by 2100 [117]. According to IMD, a heatwave is considered to be severe when the maximum temperature remains 7 deg or more above its long term normal value for an area having a normal maximum temperature ≤ 40 deg or remains 5 deg or more above its long term normal value for an area having a normal maximum temperature ≤ 40 deg [115].

Human Developmental Effects

Climate change can impact normal human developments through malnutrition during the prenatal and early childhood and through exposure to toxic contaminants and biotoxins due to extreme weather events. Environment is considered as a potential modifier of normal human development and behavior. Human development can be affected by environmental factors including subtle changes such as small reductions in IQ from exposure to lead [118], changes in onset of puberty from exposure to endocrine disrupting chemicals (EDCs) [119], birth defects such as cleft palate due to dioxin-like compounds [120] and fetal loss through exposure-related spontaneous abortion [121]. Birth defects are a leading cause of mortality accounting for 7% of all neonatal deaths and 3.3 million deaths under the age of 5 years. The prevalence of birth defects in India is 6-7% which translates to around 1.7 million birth defects annually [122] and some of these can be attributed to malnutrition arising from environmental causes. Maternal deficiencies of iodine and folic acid and other macro and micro-nutrient found to be associated with birth defects. According to the National Family and Health Survey 4 [123], less than 50% of children below 5 years of age consumed VitA rich food and only 18% consumed iron-rich foods in India. Approximately 23% of women have a BMI below 18.5, indicating a high prevalence of nutritional deficiency. Due to rising levels of CO₂ and climate change, staple crops such as rice and wheat will loss significant nutrition. According to a recent study [124] rising CO₂ levels from human activity could result in 175 million people worldwide becoming zinc deficient and 122 million people becoming protein deficient by the middle of this century and also found that over one billion women and children could lose a large amount of their dietary iron intake, putting them at increased risk of anemia and other diseases. It was also noted that India would bear the greatest burden, with an estimated 50 million people becoming zinc deficient. As many as 38

million people in India are at the risk of becoming protein deficient, and 502 million women and children becoming vulnerable to diseases associated with iron deficiency.

Climate change will lead to changes in agricultural practices and for higher crop yields increase amount of pesticides will be used which have direct human exposure. Similarly, due to the change in temperature and rainfall pattern, ranges of disease-causing mosquitoes will be expanded and control of these mosquito-borne diseases are still highly depended upon the use of a large scale of insecticides such as DDT which persists in nature for a long time. Exposure to high levels of DDT shortened menstrual cycle and reduced chance of getting pregnant. According to Cohen et al. 2003 [125], every 10 milligrams per liter of DDT in mother's serum, the probability of pregnancy for the daughter dropped by 32%. Other pesticides have also been linked to a similar reduction in fertility [126]. Additionally, changes in maternal nutrition and *in utero* exposure to certain chemicals or biotoxins due to climate change may impact the health of future generations through epigenetic changes before conception and during pregnancy.

Mental Health and Stress-Related Disorders

Mental health disorders comprise a broad class of illnesses which may even leads to chronic diseases and death. Stress-related disorders derive from abnormal responses to acute or prolonged anxiety and include diseases such as obsessive-compulsive disorder and post-traumatic stress disorder. Psychological impacts of climate change, ranging from mild stress responses to chronic stress or other mental health disorders, are generally indirect and have only recently been considered among the collection of health impacts of climate change [127]. The effects of climate change in the form of extreme weather events impact the social, economic, and environmental determinants of mental health, with the most severe consequences being felt by communities who were already disadvantaged [128]. It was observed that the tsunami associated with December 26, 2004, Sumatra–Andaman earthquake killed approximately 250000 people along the coastlines of the Indian Ocean produced posttraumatic stress reactions across a wide region of Aceh and North Sumatra [129]. Similarly, John et al. 2007 [130] observed a prevalence of 70.7% for acute posttraumatic stress disorder (PTSD) and 10.9% for delayed onset PTSD. PTSD was more prevalent among girls and more severe among adolescents exposed to loss of life or property in Tamilnadu, India. Similar high stress disorders due to that tsunami were also observed in Thailand [131] and in Sri Lanka [132].

Vector-Borne and Zoonotic Diseases

The socioeconomic development leading to the clearing of forests, reclaiming wasteland for urbanization, etc. are resulting in ecological change leading to altered epidemiology of vectorborne and zoonotic diseases (VBZD). The changes in habitats of wild animals lead to man-vector contact, thus posing a risk to public health. According to IPCC, 2007 [133], climate change is most likely to modify the consequences of vector-borne disease. Importantly, as all vector-borne diseases are extremely sensitive to climate fluctuations, these

might serve as an alert to focus attention on climate change threats [134-135]. There is substantial concern that climate change will make certain environments more suitable for some VBZD, worsening their already significant global burden and potentially reintroducing some diseases into geographic areas where they had been previously eradicated. In recent years, there is increased awareness about the resurgence of zoonotic or other re-emerging diseases in India [136]. Crimean–Congo hemorrhagic fever (CCHF) has been reported from India for the first time in 2010 while West Nile virus (WNV) is making inroads into new areas. Swine flu, which was not known till 2009, emerged in pandemic form throughout the world. The projections on climate change for India [20] indicate an increase in average temperature between 2.5°C and 5°C and an overall increase in the intensity of rainfall between 1 mm and 4 mm/day, except for small areas in north-west India. It is thought that such changes in the climate may affect several characteristics of vector-borne disease, namely their survival and reproduction rates, the intensity and temporal pattern of vector activity and the rates of development, survival, and reproduction of pathogens within vectors [133, 137].

In recent years, vector-borne diseases have emerged as a serious public health problem in countries of the South East Asia region, including India. Many of these diseases, particularly dengue fever and Japanese encephalitis, now occur in epidemic form, almost on an annual basis, causing considerable morbidity and mortality. The risk factors that play a key role in the spread and transmission of dengue and other vector-borne diseases in India and across its borders include globalization, unplanned and uncontrolled urbanization, developmental activities, poor environmental sanitation, poor household water-storage practices, improper drainage of water, widespread traveling and human migration [138]. Even the very recent outbreaks of Zika virus can be linked to the creation of suitable breeding places of Zika vector *Aedes aegypti*. Effect of climate change on different VBZD has been shown in Table 3.

Valid projections on likely impacts of climate change on VBZD are lacking, and a scientific consensus has yet to emerge. Even though we now have the technical knowledge to treat or vaccinate against many VBZD, in the absence of these technologies, some experts believe that population-level mortality from certain disease outbreaks could reach as high as 20–50%. Accordingly, this modeling method has been used particularly for malaria and dengue fever. The malaria modeling shows that small temperature increases can greatly affect transmission potential. Globally, temperature increases of 2-3°C would increase the number of people who are at risk of malaria by around 3-5%. Ultimately, projections must be specific to location, altitude, ecosystem, and host or vector. Health impacts from changing distributions of VBZD are likely to unfold over the next several decades, and prevention and control activities must be developed and honed prior to significant vector range expansion in order to be most effective [158].

Water Borne Diseases

Climate change will affect water availability but at the same time, it will also increase human exposure to unsafe water. Climate change will affect biological, physical and chemical components of water through different paths thus enhancing the risk of waterborne diseases. Water-borne disease such as cholera, diarrhea, giardiasis, salmonellosis, and cryptosporidiosis may be more frequent due to warmer climate [159].

Table 3. Impact of climate change on potential distribution and transmission of VBDs

Sl. No.	Disease	Endemic Region	Global Prevalence of Infection (in Million)	Pathways of Introduction	Vector	Possible changes in distribution as a result of Climate Change
1	Malaria*	Africa, Asia, SE Asia,	219	Infected people	Anopheles mosquitoes	More suitable in the tropical highland regions [139]
2	Lymphatic Filariasis*	Africa, South Asia, SE Asia, Asia Pacific	38,464	Infected people	Mosquitoes of genus Anopheles, Culex and Aedes	Possible expansion in tropical and subtropical regions [140,141]
3	African Trypanosomiasis	sub-Saharan Africa	0.0107	Infected people	tsetse fly (Glossina genus)	epidemics can occur when mean temperatures are between 20.7°C and 26.1°C [142] and a large shift in the geographical extent of the range [142,143]
4	Yellow fever	tropical areas of Africa and Central and South America	0.13	Infected people	Aedes aegypti	Increase in the Americas [144]
5	Muco/cutaneous Leishmaniases*	Americas, the Mediterranean basin, the Middle East and Central Asia	3.9	Infected people	female phlebotomine sandflies	likely to cause an increase in the prevalence, distribution, and severity of leishmaniases [145]
6	Visceral Leishmaniases*	Brazil, East Africa and in South-East Asia	0.061	Infected people	female phlebotomine sandflies	likely to cause an increase in the prevalence, distribution, and severity of leishmaniases [145]
7	Chagas disease	Latin America	6.653	Infected people	Triatomine bugs	A significant possibility of increase in both rural and urban population of North America [146], Decreasing trend of human infection in Latin America [147]
8	Lyme diseases	forested areas of Asia, north-western, central and eastern Europe, and the USA.	0.532	Infected people/Livestock	Ixodes scapularis, I. persulcatus, I. pacificus, I. ricinus	Increase in transmission in the USA [148] and more expansion in Europe [149]
9	Kyasanur Forest Disease	South Asia (Mainly South and West India)	NA	Infected animals (Monkeys)	Haemaphysalis spinigera	Possible range expansion within Indian subcontinent [150]
10	West Nile virus	Africa, Asia, Europe, Australia	0.002588	Migratory or dispersing birds	Mosquitoes of the genus Culex	Expansion into new areas, Increase in transmission intensities [151]
11	Japanese encephalitis virus*	South-East Asia and Western Pacific	0.0425	Infected livestock	Culex species (mainly Culex tritaeniorhynchus)	Likely to cause an increase in the prevalence, distribution, and severity in coastal areas [152]
12	Chikungunya virus*	Africa, Asia	0.693	Infected people	Ae. aegypti and Ae. albopictus	Broader expansion in tropics and subtropics [153]

Sl. No.	Disease	Endemic Region	Global Prevalence of Infection (in Million)	Pathways of Introduction	Vector	Possible changes in distribution as a result of Climate Change
13	Dengue virus*	Southern hemisphere	96	Infected people	Ae. aegypti and Ae. albopictus	Broader expansion in tropics and subtropics [153]
14	Zika virus	Africa	0.5	Infected people	Ae. aegypti and Ae. albopictus	Expected to increase in Geographical expansion due to favorable environmental conditions [154]
15	Onchocerciasis	Africa, Latin America and Yemen	15.531	Infected people	blackflies of the genus Simulium	Increase in transmission rates [155]
16	Schistosomiasis	Africa, the Middle East, the Caribbean, Brazil, Venezuela, Suriname, Indonesia, China, The Philippines	207	Infested water	Snails	Contraction in transmission in Africa [156], possibility of expansion in Asia [157]

Diseases superscripted with * are considered as major VBZD in India with their prevalences in India are: Malaria (9.5 million), Dengue (0.19 million), Chikungunya (0.07 million), Filariasis (23.0 million cses), Japanese encephalitis (0.0022 million) and Leishmaniasis (0.0058 million).

Diarrhoeal disease is one of the most important causes of mortality and morbidity in developing countries including South Asia, particularly among children [160]. It is estimated that diarrhea kills approximately 104643 (95% CI: 89525.9 – 122375.6) with a mortality rate of 84.2/100000 children below 5 years in India [161]. There is strong evidence that diarrhea, particularly the one caused by bacteria and protozoan pathogens, is highly sensitive to variations in both temperature and precipitation [162]. It is, therefore, very likely that long-term climate change will lead to consistent changes in diarrhoeal rates. Climate change can result in increased temperatures in both ocean water and ambient air as well as rise in sea level due to increased temperatures can lead to coastal flooding, which can force the communities to use contaminated water, inadequate sanitation systems, or trigger migration into areas with unsafe water and sanitation availability which can lead to the spread of Cholera [163]. Warm water, moderate salinity, and number of aquatic invertebrates are the conditions influenced by climate change which promote the growth of Cholera species. It was observed that both high and low temperatures, as well as diurnal temperature range, have been found to be associated with childhood diarrhea in Brisbane, Australia [164]. Applying the conceptual framework to the latest regional climate projections for northern India, Moors et al. 2013 [165] showed that there is a chance of increase of 5.6% and 0.4% diarrhea per 1°C rise in temperature and per mm/month decrease in rainfall respectively. The study also projected an average 13.1% increase in diarrhea incidences in north India by the 2040s.

MITIGATION AND ADAPTATION

Climate change is contributing significantly towards the global burden of disease both directly or indirectly and this contribution is expected to grow far more in the near future. According to a WHO assessment, taking into account only a subset of the possible health impacts and assuming continued economic growth and health progress, concluded that climate change is expected to cause approximately 250 000 additional deaths per year between 2030 and 2050; 38 000 due to heat exposure in elderly people, 48 000 due to diarrhoea, 60 000 due to malaria, and 95 000 due to childhood undernutrition (<https://www.who.int/news-room/fact-sheets/detail/climate-change-and-health>). Kovats et al. 2011 [166], using a medium-to-high emission (A1B) scenario with no further climate change or mitigation or adaptation efforts, resulted in estimates of an additional 26,000 deaths per year from heat by the 2020s (2011-2040), rising to 89,000 per year by the 2050s (2041-2070) and 127,000 per year by the 2080s (2071-2100). While heat-related mortality in Europe is projected to increase in all regions, there are relatively higher levels of climate change attributable heat deaths in Southern Europe. As the average mean temperature in India has increased, Mazdiyasni et al. 2017 [167], based on data from the India Meteorological Department between 1960 and 2009, indicated that there has been a substantial increase in mass heat-related deaths. Their “results suggest that even moderate increases in mean temperature may cause a great increase in heat-related mortality.” With an increase in summer mean temperature of 0.5% (to 27.5°C), the probability of these mortality events increases by a factor of 2.5 to 32%. The impacts of climate on human health will be heterogeneous around the world. Peoples living in developing countries, particularly in small island states and thickly populated coastal areas, arid and high mountain zones are considered

to be particularly vulnerable [168]. The Third Assessment Report of IPCC [169] concluded that the extent to which human health is affected depends on the exposures of populations to climate change and its environmental consequences, the sensitivity of the population to the exposure, and the ability of affected systems and populations to adapt. Certain adverse health effects can be minimized or avoided with sound mitigation and adaptation strategies. Strategies for mitigating and adapting to climate change can prevent illness and death in people now, while also protecting the environment and health of future generations. Adaptation [170] can reduce sensitivity to climate change while mitigation can reduce the exposure to climate change, including its rate and extent. Adaptation and mitigation can complement each other and together can significantly reduce the risks of climate change [171]. Appropriate mitigation and adaptation strategies will positively affect both climate change and the environment, and thereby positively affect human health. Some adaptation activities will directly improve human health through changes in our public health and health care infrastructure.

The IPCC special report on global Warming of 1.5°C [172] assesses mitigation pathways by limiting global warming to 1.5°C above pre-industrial levels which depends on the lowering green house gas emission by 2030 and reaching net zero CO₂ emission globally around 2050. The mitigation of GHGs provides a mechanism for slowing, and perhaps eventually halting the build-up of GHGs in the atmosphere. Emission of GHGs can be reduced by more efficient use of energy, reducing dependence on carbon energy and switching to low-carbon energy like solar, hydro, or wind energy, etc. Steps to reduce GHG emissions could have positive health effects. For example, promoting the safe use of public transportation and active movement, such as biking or walking as alternatives to using private vehicles, could reduce carbon dioxide emissions and improve public health. They can not only cut traffic injuries but also air pollution and associated respiratory and cardiovascular diseases. Increased levels of physical activity can lower overall mortality rates [173].

Even if GHG emissions are expected to reduce in the near future, Earth's climate will continue to change. Hence, adaptation strategies must be considered to reduce disease burdens, injuries, disabilities, and deaths. Extreme weather events can have vastly different impacts because of differences in the target population's adaptation capacity. Adaptation enhances a population's coping ability and may protect against current climatic variability as well as against future climatic changes. It includes the strategies, policies, and measures undertaken now and in future to reduce the potential adverse health effects. The rebuilding and maintaining of public health infrastructure are often viewed as the "most important, cost-effective, and urgently needed" adaptation strategy [174]. This includes public health training, more effective surveillance and emergency response systems, and sustainable prevention and control programs. Education, awareness-raising, and the creation of legal frameworks, infrastructures, institutions, and an environment that enables people to make well-informed, long-term, sustainable decisions are also of paramount importance [175] (Climate change and health: Why should India be concerned). The main determinants of a community's adaptive capacity are economic wealth, technology, information and skills, infrastructure, institutions, and equity. Adaptive capacity is also a function of current population health status and pre-existing disease burdens. Developed countries are better to adapt because they have the economic resources to invest and to offset the costs of adaptation. Countries that have contributed the majority of GHG emissions should acknowledge their responsibility for generating climate change and consequent health impacts, reduce their emissions, and support

under-resourced and marginal populations in adapting to climate change, to help ensure the long-term sustainability [176].

RESEARCH NEEDS

It is critical that adaptation and mitigation decisions and policies be developed with a sound basis in the best current science on climate change and its effects. There are gaps in our understanding of the relationship between climate change, the environment, and human health. In its 2010 report, the NIEHS-led Interagency Working Group on Climate Change and Health identified major research areas that need to be further explored and understood [158].

RESEARCH NEED IN INDIAN CONTEXT

With its huge and increasing population (~1.33 billion) and increasing rate of urbanization, India is going to witness the enormous fate of climate change which is going to magnify existing health threats by many fold [177]. A greater understanding of the relationship between climate variability and human health in a country such as India could aid in the development of new prevention strategies and early warning systems, with implications throughout the developing world. Future studies must work to more explicitly define the relationship between climate variability and emerging and reemerging infectious diseases such as dengue, yellow fever, cholera, and the chikungunya virus [178], as well as chronic diseases related to cardiovascular and respiratory illness, asthma, and diabetes [177]. Evaluation of health risks due to climatic variability and subsequent climate change by using innovative and multidisciplinary investigations coupled with environmental epidemiologic methods are important in countries like India. However, such work will require expanded partnerships among researchers, governments, and communities to develop a co-benefit strategy that addresses public health challenges and risks associated with climate change. Adoption and implementation of these research initiatives will provide the necessary tools and infrastructure to pose interesting scientific questions and design effective solutions to the complex issues imposed by climate change.

CONCLUSION

Humans are the most intelligent species on the earth and are highly adaptive. They have proved this by successfully adapting to numerous environmental changes over a long time and improving their life and health by the use of knowledge, science and technologies. These improvements come at a cost which needs to be understood and acknowledged such that human can act on it for their sustainable development. Climate change is now a mainstream issue and must be framed as a public health concern. The costs of not taking appropriate and timely action are high. Therefore, it is urgently needed to find ways to prevent the ill-effects of climate change on health and humanity by finding the knowledge gaps and adopting sustainable approaches.

Chapter 548

PUBLIC HEALTH CHALLENGES AND OPPORTUNITIES IN LEPROSY CONTROL: FROM THEORY TO IMPLEMENTATION

Yale School of Public Health, New Haven, Connecticut, USA

ABSTRACT

Despite the availability of multidrug therapy since 1981, leprosy remains a significant public health problem and cause of disability in developing countries. Progress towards the control of leprosy has stagnated: over the last ten years, the global incidence has remained around 200,000 cases, 80% of which occur in India, Brazil, and Indonesia. Control efforts have been stymied by myriad factors, including stigma, which can delay diagnosis and treatment, as well as the paucity of information about where and to what extent transmission is occurring. These challenges are exacerbated by the lack of reliable data, the absence of an appropriate measure of leprosy burden, several gaps in the epidemiological knowledge about the disease, and the high cost of implementing new control measures. To accelerate progress towards a leprosy-free world, the World Health Organization (WHO) launched a global leprosy strategy in 2016 with the goal of achieving zero disability among new pediatric patients and reducing grade-2 disability rate to less than 1 case per 1 million people by 2020. To meet these goals, expanding knowledge about leprosy epidemiology, developing innovative, evidence-based strategies and optimal implementation of current programs are essential. In this chapter, we discuss the current public health challenges that leprosy control faces, and explore the opportunities addressing these challenges that can potentially accelerate progress towards the elimination of leprosy.

INTRODUCTION

Leprosy is an infectious disease caused by *Mycobacterium leprae* that primarily affects the skin and peripheral nerves. Primary symptoms of leprosy include muscle weakness, skin lesions, and numbness in the arms and legs. Although the mechanism of disease transmission is not known, it is generally accepted that prolonged, close contact with an untreated person is needed to catch the disease [1]. Clinical manifestation of leprosy infection appears after an incubation period ranging from 2 to 20 years [2]. Leprosy patients are divided into three groups based on the number of skin lesions and infected nerves involved: paucibacillary (PB) single-lesion leprosy (one skin lesion), paucibacillary leprosy (2-5 skin lesions) and multibacillary (MB) leprosy (more than five skin lesions) [3]. Symptoms of PB infection include swelling of the nerves, muscle weakness, numbness in the limbs and stuffy nose. Compared to PB leprosy, there are many outward symptoms associated with MB leprosy, including skin lesions, curling of the fingers, ulcers, and absorption of limbs. MB leprosy progresses at a rapid rate compared to PB leprosy, and patients with MB manifestation have a lower life expectancy. MB is also associated with greater life-long disability and has a higher transmission rate than PB. The immune responses and the mechanisms involved in nerve damage caused by leprosy are not well understood, and there is no predictive test to determine the extent of nerve damage as well as the best course of the treatment regimen to minimize the damage. The disabilities caused by leprosy are often irreversible [4]. Consequently, it is necessary to diagnose and treat leprosy infections early.

The first breakthrough of disease control occurred in 1941 when sulfone was introduced as a treatment for leprosy (Figure 1). Patients treated with sulfone were instructed to continue taking the drug in smaller doses after they were released from medical care. This was followed by dapsone in 1950 (Figure 1). Dapsone treatment typically continued for 4-10 years and, in some cases, treatment continued for life. However, *M. leprae* evolved resistance to dapsone in the 1960s, which reduced the effectiveness of dapsone. To combat this problem, multidrug therapy (MDT) was recommended by the World Health Organization (WHO) in 1981 (Figure 1). Current MDT treatment to cure single lesion paucibacillary leprosy includes a combination of rifampicin, ofloxacin, and minocycline. Paucibacillary leprosy is treated with a combination of Rifampicin and dapsone. A combination of Rifampicin, clofazimine, and dapsone is used to treat multibacillary leprosy [5].

Since 1995, the WHO has supplied MDT free of cost to leprosy patients in all endemic countries (Figure 1). MDT helped reduce worldwide prevalence from more than 5.25 million cases to approximately 193,118 since 1985 [6]. Global elimination of leprosy, defined as a registered prevalence of less than 1 case per 10,000 population, was achieved in 2000 [7]. Of the 122 countries previously considered endemic for leprosy, 119 countries had achieved leprosy elimination by 2012 [8]. This dramatic reduction in prevalence is almost entirely due to the shortening of treatment duration to two years. Following evidence of low relapse rates with MDT treatment for 24 months [9], the treatment duration was further reduced to a fixed period of 6 months for PB leprosy and 12 months for MB leprosy. Widespread use of MDT also reduced the long-term cost of treatment to the health system.

Despite the substantial progress made in the last 20 years, leprosy remains a significant public health problem and the leading cause of permanent physical disabilities due to a communicable disease [10]. More than 200,000 cases are still reported worldwide every year,

with India, Brazil, and Indonesia accounting for 80% of the new cases detected globally [11]. While the global incidence of leprosy has declined by 3.4% over the last ten years, the increase in new cases was reported in 7 countries (Bangladesh, Brazil, Comoros, Mozambique, Nepal, Philippines and Sri Lanka) out of the 22 priority countries (Figure 2). Moreover, the number of new cases detected with grade-2 disability in 2017 only declined by 10% over the last 4 years from 12,267 to 11,014, indicating an urgent need to improve early case detection (Figure 3). Clearly, the transmission of leprosy is continuing. Eradication of leprosy will require increased efforts and a multifaceted strategy that addresses the myriad epidemiological, socioeconomic and clinical challenges that contribute to the persistence of leprosy. In this chapter, we review both pressing challenges and potential solutions to control leprosy.

KNOWLEDGE GAPS IN EPIDEMIOLOGY OF LEPROSY

An understanding of the transmission dynamics of leprosy is fundamental to the design and success of control strategies. However, there are gaps in our knowledge about the epidemiology of the disease. Firstly, the mechanism of leprosy transmission is not well understood. Leprosy is generally believed to spread either through direct exposure to infected fluids, indirectly via airborne viral droplets, or through direct or insect-mediated infection from zoonotic or environmental reservoirs [12]. Nasal secretions and skin of untreated leprosy patients are capable of shedding *M. leprae* to the environment. The relative potential of both the sites in establishing infection remains unclear. The ability of the disease to transmit over the course of an infection is also not known. Secondly, there is limited knowledge about risk factors for leprosy infection including genetic predisposition, immune and nutritional status [13]. Finally, there are the proportion of cases attributable to environmental reservoirs and animal hosts such as armadillos in the Americas [14, 15], red squirrels in the British Isles [16] and nonhuman primates [17].

A better understanding of *M. leprae* transmission, as well as the risk factors for infection, is essential to developing effective interventions to interrupt transmission. While the mode of leprosy transmission is unclear, prolonged, close contact with an untreated patient is likely the most common cause of transmission. Contact tracing, which involves reaching out to the contacts of index patients and screening them for signs of leprosy, can be an effective strategy of curbing leprosy transmission by enabling early diagnosis and identifying additional cases [18–21]. Research focusing on the relationship between human genetics and *M. leprae* genome has been crucial towards developing an understanding of how and why people develop leprosy [22]. There have been an increasing number of reports linking genetic regulation of the innate immune response with increased susceptibility to leprosy and also to the development of adverse leprosy reactions [23]. Advanced genome-wide association studies have provided clues towards immune-related gene variants that pose as risk factors for leprosy [24–27].

Figure 1. Timeline of key events in the history of leprosy.

Figure 2. Number of new leprosy cases across the 22 global priority countries in 2017.

CHOOSING A METRIC TO MONITOR LEPROSY CONTROL

An appropriate definition of leprosy control is fundamental to optimize strategic interventions, setting geographical priorities, and estimate the impact of intervention efforts. Prevalence has been one of the most widely used measures of monitoring leprosy burden and control. However, disease prevalence is a poor indicator of leprosy control because it is sensitive to factors such as incubation period of the disease, duration of treatment and case-finding method [28, 29]. Firstly, leprosy has a long incubation period, ranging from 2 to 20 years [30], and technology to detect leprosy at early stage is lacking. New cases therefore continue to become infectious even if prevalence may have been very low in a particular year. Secondly, with MDT, patients are declared cured after treatment and removed from leprosy registers. Consequently, shortening the treatment duration alone can dramatically reduced prevalence without reducing the number of new cases detected annually. For example, the global burden of registered leprosy cases reduced by 50% when the treatment period of leprosy decreased from 24 months to 12 months [31]. Besides prevalence, new case detection rate is increasingly used to report leprosy burden across the world. Both prevalence and new case detection rates suffer as a metric by the fact that they are strongly dependent on the surveillance efforts. Furthermore, as countries are not required to provide evidence of the quality and effectiveness of surveillance efforts, levels of under-reporting remain uncertain.

Challenges in choosing a metric to monitor leprosy control can be overcome by adopting several indicators rather than a single one. Case detection among children provides good evidence for ongoing active transmission of leprosy, and therefore new case reports among children along with disease prevalence data and detection rate can be utilized to better monitor the ongoing transmission as well as inform intervention approaches [32, 33]. Previous modeling studies have highlighted the need for active case detection [34, 35]. Such mathematical models of leprosy transmission can be further utilized to understand the current and future disease burden based on historical data and scientific knowledge about the disease.

Moreover, such studies can allow us to assess the impact of under-reporting and evaluate the effectiveness of current and future intervention strategies to curtail transmission.

SETTING A GLOBAL TARGET FOR LEPROSY CONTROL

In 1991, the WHO defined the goal of eliminating leprosy as reducing the global prevalence rate to less than one case per 10,000 population. Although the global goal was achieved in 2000, India and Brazil failed to meet the deadline. The deadline was extended to 2005 for both India and Brazil that lead to some unintended consequences. For example, India began relying on voluntary reporting and stopped actively seeking new cases and screening contacts. As a result, detection rates fell by 75% between 2003 and 2005 [36]. In India, almost half of the cases were not reported or were staged inappropriately as part of an effort to formally meet the elimination targets of 2005 [37]. Similarly, Brazil achieved the target in 2005 when unregistered patients were omitted from the calculation, which was later retracted after the missing patients were reinstated [36]. The quality of the reported data still remains a concern, especially from low-income countries. The poorest areas tend to have longer detection delays that result in larger numbers of undiagnosed leprosy cases. These undiagnosed cases remain a critical threat to the goal of breaking transmission. When countries are pressured to eliminate leprosy, inaccurate reports can ensue in an attempt to pretend to meet the goal. A study estimated that over 2.6 million cases were missed between 2000 and 2012 due to the decline in new case detection rates for meeting the Leprosy elimination target [37]. Inaccurate and under-reporting of cases not only result in continued transmission and delays in starting treatment, but also a shortage of drugs required for treatment. Therefore, it is essential to ensure that leprosy goals are transparent and widely understandable.

Setting an inappropriate global target of control can also mislead governments, health workers and donors. For example, following the achievement of previous elimination goal in 2000, political commitment, funding, and training of healthcare workers lost momentum, even though more than 700,000 new cases were registered in the same year [10, 36, 38]. The decreased incentive to find new cases may partly explain the 38% increase in grade-2 disability cases from 2004 - 2007. Recognizing these challenges and shortcomings of defining goals based on elimination, the WHO shifted its future goal towards reducing the global burden and reduction of grade-2 disabilities. The 2016-2020 Global Leprosy Strategy aims to reduce the newly detected cases with leprosy-related deformities to below 1 per million population at the global level by 2020 and to reduce leprosy-affected disabilities in children to zero. The WHO's new goal of reducing the grade-2 disability rate will be challenging, considering uncertainties about data quality. Tools and measurement techniques for collecting disability data exist, but their applicability to leprosy-endemic countries needs to be validated [39].

CLINICAL SHORTCOMINGS

Currently, the evidence of acid-fast bacilli in slit-skin smears or the presence of characteristic histological patterns of nerves or skin through biopsy is used to confirm a diagnosis of leprosy. However, the presence of bacilli is rare in the PB forms of the disease and in some cases typical histopathologic changes may not be present [40]. Therefore, there is no gold standard for accurately diagnosing and classifying leprosy so far. Moreover, there are no serologic tests that are available for the routine laboratory diagnosis.

In the absence of any point-of-care test, the initial diagnosis of leprosy commonly relies on the patient's clinical signs and symptoms. In an endemic area, WHO recommends considering an individual as having leprosy if they have skin lesions consistent with definite sensory loss, with or without thickened nerves and positive skin smears. The clinical symptoms are determined by a skin and neurological exam. Additionally, skin biopsies and smears may also be taken to provide a more conclusive diagnosis. Other more uncommon tests include nasal smears, nerve biopsies, and blood exams. Based on the number of bacteria, either PB or MB leprosy is diagnosed [41].

Since leprosy patients have traditionally been in the hands of specialized staff, many healthcare providers are ill-equipped to treat leprosy patients. Success in meeting the World Health Organization's (WHO) goal of eliminating leprosy as a global public health problem by 2005 also led to complacency and a loss of skills in diagnosing and managing leprosy patients. Although the integration of leprosy services into public health services helps reduce stigma, there is a loss of skill in diagnosis and treatment. [42]. Lack of diagnosis and management skills is exacerbated by the fact that, even if a clinical diagnosis is made, there is no good point-of-care test for confirming it. [43]. Tests to confirm a leprosy diagnosis such as skin smears and skin biopsies are only available in facilities that have labs. Unavailability of such facilities can also lead to patients being diagnosed with a disease other than leprosy by their healthcare providers. 42.6% of participants in a study among patients across three states of Brazil were misdiagnosed initially, suggesting a need to increase clinical suspicion of leprosy [44].

In order to both curb transmission and prevent disabilities, it is essential to focus on research aimed at finding practical diagnostic tools that can detect all levels of leprosy infections. Several serological tests for leprosy detection are under development but none of them have achieved sufficient sensitivity and specificity yet [42]. Integrating leprosy services in primary health care can improve case finding and continuity of care, however without appropriate expertise, misdiagnosis of leprosy can not be minimized. Therefore, it is vital to provide clinicians training to recognize and diagnose leprosy, especially in high-risk regions.

STIGMA OF LEPROSY

Although leprosy has had a widespread prevalence since medieval times, and there is evidence of the disease as far back as 1600 BC, it was not until 1873 that *M. leprae* was discovered as the cause of leprosy. While this discovery dispelled the myth that leprosy was hereditary or a curse, the stigma associated with the disease persisted. Fuelling the stigma, legal discrimination against people affected by leprosy played a key role in outcasting leprosy

patients from society. For example, segregation of people with leprosy was required by law in Japan and leprosy patients begged for a living around the temples or shrines. Starting in 1909, the Japanese government started hospitalizing leprosy patients in the leprosy sanatoria, often forcefully. This law lasted until 1996 [45]. Similarly, British India enacted the Leprosy Act of 1898, which institutionalized those affected and segregated them by sex to prevent reproduction. The law also stated that a state government could declare any place as an asylum for people with leprosy. In addition, a sequel to the law said that any person with leprosy who appeared to be poor could be arrested without a warrant. This law was repealed only in 1983 [46].

Although legal discrimination against leprosy patients has reduced significantly across the world, the social stigma against people with leprosy continues to drive affected individuals into further poverty by limiting their employment and educational opportunities. Because MB leprosy shows more outward signs of the disease, people with MB leprosy are stigmatized more than people with PB leprosy. Stigma also deters people from seeking treatment that subsequently leads to irreversible disabilities, such as nerve damage [42]. Delayed treatment also increases the risk of transmission to other people. While active case finding can curb transmission in areas where stigma is widespread, efforts to reduce social stigma towards leprosy patients will have a long-lasting impact on surveillance and control of leprosy.

The stigma associated with the disease is deeply rooted in societies across the world through centuries of misconceptions and myths. The lack of knowledge about the etiology, curability, and transmissibility of the disease remains one of the driving factors of social stigma faced by leprosy patients. Therefore, interventions to raise community awareness by demystifying misconceptions such as leprosy being hereditary or leprosy cases being untouchable can be highly effective. Similarly, it is imperative to train healthcare officials and staff to ensure non-discriminatory behavior of healthcare workers while diagnosing and treating leprosy patients. Integrating leprosy services in general health care aimed towards ‘no isolation-no discrimination’ policy can gradually decrease society’s negative perception as well as provide treatment to leprosy patients closer home.

Fear of social exclusion plays a fundamental role in leprosy patients delaying seeking treatment. The deformity caused by leprosy in a patient not only limits their employment opportunities, but it also results in decreased prospects of marriage for them and their family members. Strategies that primarily focus on reintegration of people with leprosy into society such that they can live with dignity and self-sufficiency are essential to improve their quality of life and to encourage individuals with symptoms to seek early treatment.

The WHO’s Global Leprosy Strategy 2016-2020 calls for several measures to end discrimination towards those affected by leprosy [47]. These measures include empowering the leprosy patients and their communities to actively participate in leprosy programs, providing better access to social and financial support, and promoting community-based rehabilitation for people with leprosy-related disabilities. The WHO has also committed to work towards ending discriminatory laws and promoting policies that facilitate the inclusion of people affected by leprosy.

SOCIOECONOMIC RISK FACTORS

Although leprosy has been identified as a disease of poverty, we still have a limited understanding of the risk factors that link them together. Nationally, new case detection rates do not necessarily correlate with indicators such as GDP or human development index. For example, countries with very low human development index such as Burkina Faso (ranked 183) and Benin (ranked 163) report lower new case detection rates compared to Brazil (ranked 79) that has the second highest new case detection rates [48]. The distribution of leprosy risk is highly heterogeneous even within most affected countries such as India, Brazil and Indonesia where the majority of cases occur in high-risk regions. Living in a crowded household as well as lack of schooling was identified as a risk factor in an individual-level study done in Malawi [49]. Another study conducted in a high endemic area of leprosy in Brazil showed the level of inequality, population growth, and presence of a railroad are associated with higher levels of leprosy [50]. A systematic review and meta-analysis of 39 studies identified poor hygiene, lower levels of education, and food insecurity as risk factors for leprosy [51].

Across all high-endemic regions of leprosy, impoverished communities remain disproportionately affected. Multiple socioeconomic factors drive the association between leprosy and poverty. One of these factors is the lack of physical access to diagnosis and treatment, which occurs due to inadequate access to specialized leprosy clinics. The costs of seeking treatment are another factor. Although MDT is free, other costs such as travel, lost wages, and other incidental expenses must be accounted for. In addition, getting MDT to patients—who are typically located in impoverished remote locations—poses major logistical and distribution challenges. Shortages of MDT at the health center level are a chronic problem due to weak information systems and inadequate planning. Moreover, when the disease has progressed too far, MDT may not be sufficient to prevent permanent disabilities.

Figure 3. Number of new leprosy cases diagnosed with grade-2 disabilities across the 22 global priority countries in 2017.

Most of these challenges emphasize the importance of efficient, cost-effective case detection in high-endemic regions. The status quo approach of passive case finding that relies on people with symptoms to voluntarily present themselves at health-care facilities is ill-suited to curb transmission. Delayed treatment also increases the risk of permanent disabilities. Targeted strategies of diagnosing cases in high-risk areas have the potential to accelerate leprosy control. By facilitating early diagnosis and treatment, targeted case-finding approaches can substantially curtail transmission and reduce disabilities among leprosy patients. Socioeconomic factors associated with high risk can of leprosy infection be used to target diagnostic efforts and interventions that will be fundamental to curb leprosy transmission. Moreover, improving health-care access and implementing poverty alleviating interventions among the most vulnerable populations in leprosy-endemic regions can facilitate leprosy control.

CONCLUSION

Leprosy, an age-old disease caused by *Mycobacterium leprae*, is no longer causing the level of devastation it had for thousands of years. Since multidrug therapy became available for widespread use in the early 1980s, over 16 million people have been successfully treated for leprosy [52]. Consequently, leprosy prevalence has dropped by 99% over the last thirty years: from 21.1 cases per 10,000 population in 1985 to 0.2 cases per 10,000 population in 2015 [52]. Progress towards leprosy control, however, has stagnated due to continuing and interrelated challenges of clinical uncertainties, knowledge gaps in epidemiology of leprosy, stigma, delayed diagnosis, and socioeconomic risk factors [53].

A multifaceted approach that mitigates the existing challenges and improves early case-detection, provides effective treatment and reintegrates leprosy patients in the society will be required to curtail leprosy at local and global levels. It is vital to identify the pockets of high endemicity in each country. Intervention efforts can be most effectively and efficiently targeted to these areas where high-risk population reside. Innovative technologies are needed to generate high quality and high-resolution data on new case detection rates and prevalence. Epidemiological studies can utilize these data to identify factors that are associated with a high risk of leprosy and to map the regions where control efforts are most needed. For example, a recent systematic review and meta-analysis of socioeconomic determinants revealed several risk factors, including crowded living conditions, food insecurity, household exposure, manual labor, increasing age, lack of sanitation, and lower levels of education [51].

Untrained healthcare professionals contribute substantially to delays in case detection due to both misdiagnoses of early-stage symptoms and discriminatory behavior towards leprosy patients. Training and sensitizing healthcare workers to create a nondiscriminatory healthcare environment will reduce misdiagnosis of cases and encourage patients with symptoms to seek treatment sooner. Delays in diagnosis can also be reduced by alleviating the social stigma faced by patients. Awareness campaigns can aid in reducing societal stigma and contribute to accelerating case-detection and preventing leprosy-related deformities in patients. In the absence of quick point-of-care tests for confirming leprosy, setting up a sufficient number of laboratories with facilities to conduct skin and nerve biopsy and acid-bacilli tests can also

improve case-detection rates. Given that leprosy is a disease of poverty, social development should help to reduce leprosy risks and facilitate eradication.

As leprosy has a very long incubation period, rigorous surveillance and contact tracing are of utmost importance to curb transmission in communities where leprosy cases have been reported. The WHO recommends examining the members of a patient's household for signs of leprosy and educating them on the initial signs. The approach can be further strengthened by continued periodic inspections of family members by medical professionals. At the community level, active case finding should be implemented in areas from leprosy cases are being reported. Awareness campaigns can educate communities to recognize the first signs of symptoms so that they can seek medical care promptly before permanent disabilities occur or there is a further onward transmission. In areas that have previously reported cases, surveillance can be implemented via periodic active case finding among school children to monitor leprosy transmission. The government of countries with leprosy should frame health policies that are geared towards reducing transmission.

The treatment-as-prevention approaches that have been successful in curtailing HIV transmission are applicable to leprosy. Chemoprophylaxis, a treatment that prevents infection for about two years, is an option that can significantly lower the risk of leprosy acquisition among contacts of leprosy patients. However, the widespread use of chemoprophylaxis is still being debated due to ethical and logistical concerns [42, 54]. Two doses of chemoprophylaxis, as opposed to one, would be most effective, but chemoprophylaxis is expensive and is not widely available [54]. Cost-effectiveness studies can evaluate and optimize strategies to treat and household contacts of leprosy patients using chemoprophylaxis. Furthermore, the *Bacillus Calmette–Guérin* (BCG) vaccine, which provides protection against tuberculosis, has also been found to be partially efficacious against leprosy [55]. Thus, BCG vaccination coverage levels should be assessed among populations that are at high risk of leprosy. Improving BCG vaccination among individuals at high risk of leprosy can be a cost-effective strategy for averting cases of leprosy and ultimately reducing prevalence.

Following the introduction of MDT, leprosy prevalence declined sharply between 1980 to 2010. The positive impact of widespread use of MDT appears to have run its course and despite continued efforts, leprosy prevalence has remained stable for the last several years. There is a need for new innovative tools that can detect leprosy infection early, including subclinical infection, and tracking drug resistance. Additionally, new avenues for basic science and clinical research have been opened by genome sequencing of *Mycobacterium leprae* and genome-wide analysis for leprosy cases, which could be instrumental in the development of drugs and vaccines. Until such breakthroughs in clinical research are achieved that can augment the current strategies and facilitate the elimination of leprosy, interrupting leprosy transmission will require bolstering skills in leprosy diagnosis and management, rigorous surveillance and contact tracing of cases, and development of a point-of-care test for confirming leprosy diagnosis.

Chapter 549

**PUBLIC HEALTH PREPAREDNESS:
HHS SHOULD TAKE ACTIONS TO ENSURE IT HAS AN
ADEQUATE NUMBER OF EFFECTIVELY TRAINED
EMERGENCY RESPONDERS***

United States Government Accountability Office

ABBREVIATIONS

ASPR	Office of the Assistant Secretary for Preparedness and Response
HHS	Department of Health and Human Services
NDMS	National Disaster Medical System

WHY GAO DID THIS STUDY

NDMS is the main program through which HHS enrolls responders to assist with the federal medical and public health response to public health emergencies. HHS deploys NDMS responders to provide, among other things, patient care and movement.

During the 2017 hurricanes, NDMS had a shortage of responders that resulted in HHS relying on other departments, such as the Department of Defense, to provide medical care. As of December 2019, HHS had 3,667 NDMS responders.

The Pandemic and All-Hazards Preparedness and Advancing Innovation Act of 2019 included a provision for GAO to review HHS's responder surge capacity. This report examines (1) the workforce planning for NDMS responders to assist with public health emergencies, and (2) training provided to these responders.

* This is an edited, reformatted and augmented version of United States Government Accountability Office, Report to Congressional Committees, Publication No. GAO-20-525, dated June 2020.

To conduct this work, GAO reviewed agency NDMS planning documentation, including NDMS staffing decisions, team structures, and training materials; compared HHS actions to key workforce planning practices; and interviewed HHS officials.

WHAT GAO RECOMMENDS

GAO is making five recommendations to HHS, including to develop a workforce target that accounts for the critical skills and competencies that are needed to meet current and future programmatic results and to develop processes for evaluating its training to ensure an effectively trained workforce. HHS concurred with our recommendations and generally plans to take action.

WHAT GAO FOUND

Major natural disasters in the past 3 years, as well as the COVID-19 pandemic, have heightened attention to the nation's ability to respond to these types of emergencies. The Department of Health and Human Services (HHS) is responsible for leading the public health and medical response to emergencies. HHS responded to COVID-19, in part, by deploying responders enrolled in the National Disaster Medical System (NDMS). These individuals, such as doctors and nurses, generally work outside the federal government and are federal employees used intermittently. In 2018, HHS developed an enrollment target for NDMS of 6,290 responders, but GAO found HHS did not follow key principles of effective strategic workforce planning in developing this target. For example, HHS did not identify the critical skills and competencies needed of its NDMS workforce to meet current and future programmatic results. Specifically, HHS's target does not take into consideration three key areas: a workforce capable of responding to (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders.

Consequently, HHS cannot be sure its target, if achieved, will provide an adequate number of responders with the skill sets needed to effectively respond.

Source: Department of Health and Human Services. | GAO-20-525.

HHS requires responders to take web-based training prior to deployment, such as characteristics of infectious diseases, and also offers optional in-person training, such as care delivery in a severe environment. However, HHS's process to evaluate its training does not align with key practices. As a result, HHS does not have assurance that it is effectively preparing responders for deployment, including keeping them and others safe during an emergency, such as COVID-19. For example, HHS requires a web-based course on donning and doffing personal protective equipment to protect against infectious disease, biological, and chemical threats. However, HHS does not know the training's effectiveness until responders have deployed; at which point, if ineffective, responders could potentially expose themselves to hazards. Further, HHS officials state their in-person training is most beneficial but more costly to provide, limiting its provision. A more effective training evaluation process would help the agency determine which in-person courses are most beneficial and should be prioritized, or even made mandatory, for effective and safe responder deployment.

June 18, 2020

The Honorable Lamar Alexander
Chairman
The Honorable Patty Murray
Ranking Member
Committee on Health, Education, Labor & Pensions
United States Senate

The Honorable Frank Pallone, Jr.
Chairman
The Honorable Greg Walden
Ranking Member
Committee on Energy & Commerce
House of Representatives

On January 31, 2020, the Secretary of Health and Human Services declared a public health emergency for the United States to aid the nation's health care community to respond to Coronavirus Disease 2019 (COVID-19).¹ On March 11, 2020, the World Health Organization characterized COVID-19 as a pandemic. Subsequently, on March 13, 2020, the President declared COVID-19 a national emergency under the National Emergencies Act and an emergency under the Robert T. Stafford Disaster Relief and Emergency Assistance Act.²

To aid the response to COVID-19, as of March 27, 2020, the Office of the Assistant Secretary for Preparedness and Response (ASPR), a division within the Department of Health and Human Services (HHS), deployed about 1,200 public health and medical responders through its National Disaster Medical System (NDMS), according to ASPR officials. These individuals, such as doctors, nurses, and paramedics, work outside the federal government on a day-to-day basis and are federal employees used intermittently to respond to public health

¹ The declaration was retroactive to January 27, 2020.

² The President has also approved major disaster declarations under the Robert T. Stafford Disaster Relief and Emergency Assistance Act for all 50 states, the District of Columbia, and five territories.

emergencies. Some of these responders deployed to help disembark American citizens who were potentially infected with COVID-19 aboard cruise ships, including the Diamond Princess in Japan and the Grand Princess in California, to their quarantine locations in the United States.

ASPR previously deployed these responders to provide surge support as part of the federal public health and medical response to the 2017 hurricanes affecting Texas, Puerto Rico, Florida, and the U.S. Virgin Islands. However, we reported in 2019 that during the hurricane response, ASPR experienced a shortage of NDMS responders and relied on its federal partners, such as the Department of Defense, to provide medical response personnel.³ These events and others have raised questions about ASPR's public health and medical responders, including their capacity to assist during public health emergencies, such as the COVID-19 pandemic, as well as natural disasters, the number of which are predicted to rise as the climate changes.⁴

ASPR leads the nation's medical and public health preparedness for, response to, and recovery from public health emergencies. As part of this role, ASPR aims to enhance medical surge capacity by organizing, training, and equipping federal public health and medical responders, as well as calling upon and deploying these personnel during responses.

The program through which ASPR enrolls responders is NDMS. ASPR may activate NDMS to deploy medical providers, evacuate patients, and provide veterinary services, among other supports.⁵

The Pandemic and All-Hazards Preparedness and Advancing Innovation Act of 2019 included a provision for GAO to review the federal medical provider surge capacity in the event of a public health emergency.⁶ This report examines

1. ASPR's workforce planning for its medical and public health responders to assist with public health emergencies, and
2. ASPR's evaluation of, and planning for, the training it provides to its medical and public health responders.

To examine ASPR's workforce planning for its medical and public health responders to assist with public health emergencies, we reviewed ASPR documentation and interviewed ASPR officials involved with workforce planning for, and hiring of, NDMS responders.

³ GAO, Disaster Response: HHS Should Address Deficiencies Highlighted by Recent Hurricanes in the U.S. Virgin Islands and Puerto Rico, GAO-19-592 (Washington, D.C.: Sept. 20, 2019).

⁴ According to a 2018 report from the U.S. Global Change Research Program, extreme weather and climate-related events are expected to increase in frequency and intensity. U.S. Global Change Research Program, Impacts, Risks, and Adaptation in the United States: Fourth National Climate Assessment, Volume II (Washington, D.C.: 2018). We have also reported that the number of disasters and the reliance on the federal government for disaster assistance will likely continue to rise as the climate changes. GAO, Climate Change: Information on Potential Economic Effects Could Help Guide Federal Efforts to Reduce Fiscal Exposure, GAO-17-720 (Washington, D.C.: Sept. 28, 2017). Managing fiscal exposure due to climate change has been on our high-risk list since 2013, in part, because of concerns about the increasing costs of disaster response and recovery efforts. See GAO, High-Risk Series: Substantial Efforts Needed to Achieve Greater Progress on High-Risk Areas, GAO-19-157SP (Washington, D.C.: March 6, 2019); also http://www.gao.gov/highrisk/limiting_federal_government_fiscal_exposure/why_did_study.

⁵ Under 42 U.S.C. § 300hh-11, NDMS may be activated to provide health services, health-related social services, other appropriate human services, and appropriate auxiliary services to respond to the needs of victims of a public health emergency. ASPR may also activate NDMS in a location that is at-risk of an emergency.

⁶ Pub. L. No. 116-22, § 301(e), 133 Stat. 905, 933-34.

Specifically, we reviewed a June 2018 staffing decision memo signed by the Assistant Secretary for Preparedness and Response outlining ASPR's target for NDMS enrollment—referred to as the NDMS workforce target for the purposes of this report. We reviewed NDMS team structures that the agency developed in March 2018, which include position types and numbers of responders in each position. We also reviewed direct-hire authorities HHS received to hire NDMS responders.⁷ Further, we collected and analyzed ASPR data on the number of enrolled NDMS responders. We assessed the reliability of these data by comparing them to data in other sources, such as agency budget justifications, interviewing knowledgeable agency officials, and performing checks of the data for consistency and completeness. Based on these steps, we found these data to be reliable for our reporting purposes. Lastly, we interviewed ASPR officials to gather information on the capacity factors they considered when establishing the NDMS workforce target and the related workforce planning the agency has conducted. We also interviewed officials from HHS's Staffing Recruitment and Operations Center—the office that conducts all hiring actions on behalf of ASPR and certain other HHS divisions—to gather information on the planning and hiring process for NDMS responders.

We assessed ASPR's workforce planning against key principles of strategic workforce planning that we have identified in previous work, focusing our analysis on those principles that are related to determining current and future workforce needs and establishing strategies to fulfill those needs.⁸ This was a general all-hazards assessment of ASPR's workforce planning and not specific to a single event. In addition to NDMS, the U.S. Public Health Service—an agency within HHS—can also deploy Commissioned Corps officers as a means to help surge during a medical and public health response to an emergency or disaster.⁹ We did not assess the workforce planning of the Public Health Service because the agency is in the process of reorganizing its workforce. This includes plans for implementing a Ready Reserve Corps, which like NDMS, would consist of intermittent employees who could be called-up as needed. For more information on these plans, as well as the number of U.S. Public Health Service Commissioned Corps officers available to provide medical and public health care to humans during a response, see appendix I.

To examine ASPR's evaluation of, and planning for, the training provided to its responders, we reviewed ASPR's current NDMS training catalog, which covers fiscal years 2017-2019 and its draft NDMS training catalog, which the agency plans to implement for

⁷ A direct-hire authority is generally provided to federal agencies when a critical hiring need or severe shortage of candidates exists to expedite hiring by eliminating competitive rating and ranking, among other competitive appointment procedures. HHS received a direct hiring authority for NDMS that ran from February 9, 2018, to November 6, 2018, as part of the Bipartisan Budget Act of 2018. Pub. L. No. 115-123, § 20803, 132 Stat. 64, 95. The Bipartisan Budget Act of 2018 made supplemental appropriations to aid the response to the 2017 hurricane season. HHS received another direct hiring authority as part of the Pandemic and All-Hazards Preparedness and Advancing Innovation Act of 2019. Pub. L. No. 116-22, § 301(a)(3), 133 Stat. 932 (codified at 42 U.S.C. § 300hh-11(c)(4)). This direct hire authority began on June 24, 2019 and ends on September 30, 2021.

⁸ GAO, *Human Capital: Key Principles for Effective Strategic Workforce Planning*, GAO-04-39 (Washington, D.C.: Dec 11, 2003).

⁹ Commissioned Corps officers may be deployed to respond to an urgent or emergency public health care need arising from (1) a national emergency declared by the President under the National Emergencies Act; (2) an emergency or major disaster declared by the President under the Robert T. Stafford Disaster Relief and Emergency Assistance Act; (3) a public health emergency declared by the Secretary of Health and Human Services under the Public Health Service Act; or (4) any emergency that is appropriate for deployment, as determined by the Secretary of Health and Human Services. See 42 U.S.C. §§ 204a(a)(5) and 215(e).

fiscal years 2020-2024 but had not yet implemented at the time of our review. These training catalogs describe mandatory and optional NDMS training courses. We also compared ASPR documentation on the number of optional training courses the agency had planned to provide in fiscal year 2019 against documentation of courses actually provided in that year. Further, we analyzed ASPR's efforts to evaluate its training. This included a review of the survey questions ASPR provides to training participants to evaluate the training they have received. Lastly, we interviewed ASPR officials who oversee NDMS training. We assessed ASPR's planning and evaluation of NDMS responder training against GAO-identified key practices for effective training programs and key principles of strategic workforce planning.¹⁰

We conducted this performance audit from July 2019 to June 2020 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

BACKGROUND

Medical and Public Health Responders

As of December 9, 2019, ASPR had 3,667 enrolled NDMS responders. These responders include physicians, nurses, and paramedics, among other professions, who generally work outside of the government but may be asked to deploy to assist with a federal public health emergency.¹¹ Because these individuals have regular jobs, they may not always be available to deploy. For example, if a response occurs in a state, NDMS responders in that state may already be assisting the response through their civilian jobs, such as through working in hospitals, hindering their ability to deploy.

NDMS responders are organized into five types of NDMS teams. Two of these types—the Disaster Medical Assistance Team and the Trauma and Critical Care Team—are primarily composed of medical providers and focus on providing public health and medical care to individuals during a response. The other three types of teams are the Disaster Mortuary Operational Response Team, the Victim Information Center Team, and the National Veterinary Response Team. See Table 1 for a description of each type of team and number of responders enrolled in each.

¹⁰ See GAO, *Human Capital: A Guide for Assessing Strategic Training and Development Efforts in the Federal Government* (Supersedes GAO-03-893G), GAO-04-546G (Washington, D.C.: Mar. 1, 2004) and GAO-04-39.

¹¹ According to agency officials, responders are federal employees used intermittently and are entitled to the same liability and workforce protections offered to full-time federal employees when deployed due to their positions as intermittent federal employees.

Table 1. Types of National Disaster Medical System (NDMS) responder teams

NDMS Team Name	Team Description	Number of responders ^a
Disaster Medical Assistance Team	Provide patient care to help area health systems during a response. Responders include advanced clinicians (nurse practitioners/physician assistants), physicians, registered nurses, respiratory therapists, paramedics, pharmacists, safety specialists, logistical specialists, information technologists, and communication and administrative specialists.	2,703
Trauma and Critical Care Team	Provide critical, operative, and emergency care to help people during a response. Responders are medical professionals with expertise in trauma care.	212
Disaster Mortuary Operational Response Team	Identify victims and support local mortuary services. Responders include funeral directors, medical examiners, pathologists, forensic anthropologists, fingerprint specialists, forensic odontologists, dental assistants, administrative specialists, and security specialists.	611
Victim Information Center Team	Support local authorities and other NDMS teams in the aftermath of a mass casualty event and may serve as liaison to victims' families. Responders, who include forensic dental officers, pathologists, and victim advocates, collect ante-mortem data, such as pictures, fingerprints, dental X-rays, and other medical records, to help identify the victims.	51
National Veterinary Response Team	Provide veterinary care to working animals, such as search and rescue dogs, during disasters and certain national security events. Responders include veterinarians, animal health technicians, epidemiologists, safety specialists, logisticians, communications specialists, and other support personnel.	90

Note: ^aData as of December 9, 2019.

Workforce Planning and Training

We have previously reported that high-performing public organizations have found that maintaining a quality workforce requires them to systematically assess current and future workforce needs and formulate a long-term strategy to attract, retain, develop, and motivate employees.¹² While simple in theory, strategic workforce planning can be difficult to carry out. Agencies must, for example, acquire accurate information on the workforce, including assessing the workforce's ability to assist with mission achievement. Further, agencies must have the internal capabilities to support strategic workforce planning activities. According to our previous work, strategic workforce planning should involve certain key principles that agencies should address, irrespective of the context of the workforce planning. Among these principles are the need to align workforce requirements with agency-wide goals and objectives, identify critical skills and competencies the workforce needs to meet current and future programmatic results, and develop strategies to fill identified gaps in these skills. Effective strategic workforce planning enables an agency to remain aware of, and be prepared for, its current, emerging, and future needs as an organization.¹³

¹² GAO, *Veterinarian Workforce: Actions Are Needed to Ensure Sufficient Capacity of Protecting Public and Animal Health*, GAO-09-178 (Washington, D.C.: February 4, 2009).

¹³ GAO-04-39.

We have also reported that strategic workforce planning includes the training and development of the workforce to eliminate gaps and improve the contribution of critical skills and competencies needed for mission success.¹⁴ Agencies need to ensure that training provided is strategically targeted and not wasted on efforts that are irrelevant, duplicative, or ineffective. Effective training and development programs are an integral part of a learning environment that can enhance the federal government's ability to attract and retain employees with the skills and competencies needed to achieve results for the benefit of the American people.

According to our previous work, key practices for effective training programs involve evaluating training, such as using measures of (1) training participants' reaction to, and satisfaction with, the training program and (2) changes in participants' knowledge, skills, abilities, and on-the-job behavior. Key practices also include planning for training, such as prioritizing training around funding so that an agency can address its most important training needs first.¹⁵

ASPR IS MISSING KEY STEPS IN WORKFORCE PLANNING, LIMITING ASSURANCE THAT IT CAN ADEQUATELY RESPOND TO PUBLIC HEALTH EMERGENCIES

ASPR has not conducted key workforce planning steps for its NDMS responder workforce, and as a result, has limited assurance that it is adequately prepared to respond to public health emergencies. While ASPR has performed some workforce planning, the agency's efforts do not follow the strategic principles that we have identified in prior work as essential for effective workforce planning.

Specifically, ASPR's primary workforce planning efforts focused on developing an NDMS workforce target of 6,290 responders. ASPR data shows that it had reached a little more than half of this target, with 3,667 responders enrolled in NDMS as of December 2019. According to ASPR officials, this workforce target represents the number of responders the agency estimates it needs to enroll in NDMS to position itself to effectively respond to public health emergencies.

ASPR generated this target in June 2018 by multiplying the number of NDMS teams it had at that time by the number of responders planned for each of the five NDMS team types, using NDMS team structures that ASPR developed in March 2018—which include position types and numbers of responders in each position. (See appendix II for the NDMS team structures for each of the five NDMS team types.) See Table 2 for ASPR's workforce target for each of the five NDMS team types.

However, we found that by using this process to determine its workforce needs, ASPR has limited assurance that reaching its NDMS workforce target will be adequate to allow the agency to respond effectively to public health emergencies. This is because, when setting its target, ASPR has not followed two key principles of strategic workforce planning: aligning workforce requirements with agency-wide goals and objectives, and identifying critical skills

¹⁴ GAO-04-546G.

¹⁵ GAO-04-546G.

and competencies the workforce needs to meet current and future programmatic results. Further, even if ASPR’s target is adequate, its ability to achieve this target is limited, because ASPR has not followed a third key strategic workforce planning principle: developing strategies to fill identified gaps in these skills. These key principles are described below, along with an assessment of ASPR’s efforts.

Table 2. ASPR’s workforce target, by National Disaster Medical System team type

Team type	Number of teams as of June 2018	Number of responders ASPR would like, per team	Workforce target = number of teams x number of responders per team
Disaster Medical Assistance Team	57	85	4,845
Trauma and Critical Care Team	3	118	354
Disaster Mortuary Operational Response Team	10	86	860
Victim Identification Team	1	52	52
National Veterinary Response Team	1	179	179
Total			6,290

Alignment between ASPR’s NDMS Workforce Target and APSR’s Agency-Wide Goals And Objectives Has Been Limited

According to key principles of effective workforce planning, the process begins with an agency setting a strategic direction and aligning its workforce requirements with agency-wide goals and objectives. However, we found that the extent to which ASPR aligned its NDMS workforce target with APSR’s agency-wide goals and objectives has been limited, because the agency has not had a strategic plan with specific objectives since 2016. According to agency officials, the prior strategic plan expired while the agency was under an acting Secretary, and development of a new strategic plan led by the current Assistant Secretary for Preparedness and Response, who began his role in August 2017, has been delayed due to events, such as the 2017 hurricanes. Agency officials told us that they had planned to release a strategic plan in April 2020, but at the time this report was being prepared to be published, ASPR’s strategic plan had not yet been released.

In lieu of a strategic plan, ASPR officials told us that they aligned the NDMS workforce target with four broad guiding priorities published on ASPR’s website: (1) providing strong leadership, (2) building a regional disaster health response system, (3) sustaining public health security capacity, and (4) enhancing the medical countermeasure enterprise.¹⁶ However, officials provided conflicting information regarding where NDMS responders fit within ASPR’s four priorities. When we asked program officials who oversee NDMS where the program falls within these priorities, these officials told us that NDMS was associated with priority 1 – providing strong leadership, and indirectly related to priority 2 – building a

¹⁶ ASPR, *ASPR Mission and Priorities*, accessed April 24, 2020, <https://www.phe.gov/about/aspr/Pages/About-ASPR.aspx>.

regional disaster health response system. ASPR officials in the Office of Strategy, Policy, Planning and Requirements told us that NDMS falls under priority 2. ASPR officials told us that this misalignment occurred because leadership developing the agency-wide strategic plan had not informed the NDMS program officials of where NDMS fell within the priorities.

In March 2020, ASPR officials provided us with a draft version of the agency's forthcoming strategic plan. In this draft plan, ASPR lists the following four priority goals, which are similar to those the agency has been operating under, albeit in a different order: (1) foster strong leadership, (2) sustain a robust and resilient public health security capacity, (3) advance an innovative medical countermeasure enterprise, and (4) build a regional disaster health response system. From reviewing this plan, it is clear that NDMS falls within priority 4 – building a regional disaster health response system, as one of the objectives is “modernize NDMS.” However, NDMS also falls within an objective under priority 2, “strength response and recovery operations,” as well as an objective under priority 1, “lead adaptive planning and emergency repatriation efforts.” In finalizing this strategic plan, aligning the NDMS workforce target with ASPR goals and objectives would help ensure mission clarity and accountability. Without such an NDMS workforce target, ASPR risks being unable to fulfill its role as the lead agency for public health emergencies, which includes the ability to sufficiently enhance medical surge capacity during a response.

ASPR's NDMS Workforce Target Did Not Adequately Identify Critical Skills and Competencies Needed to Meet Current and Future Programmatic Results

According to key principles of effective workforce planning, an agency should identify the critical skills and competencies needed of its workforce that will position it to meet current and future programmatic results. The NDMS team structures that ASPR developed in March 2018 broadly cover emergency response needs for medical and public health care by including position types and number of responders needed in each position.

However, ASPR's process for calculating its responder workforce target did not take into consideration three key workforce factors: specifically, a workforce capable of responding to (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders, all of which would help determine the NDMS workforce skills and competencies needed to meet current and future programmatic results.

- *Number of responders needed for a nationwide event or multiple concurrent events.* ASPR did not consider the number of responders projected to be needed to respond to multiple or concurrent events, such as the 2017 hurricanes, or a national event, such as an infectious disease outbreak, when developing the NDMS workforce target. This is notable given that during the 2017 hurricane season, we found that ASPR experienced a shortage of NDMS responders, which contributed to a reliance on the Department of Defense to provide essential public health and medical service functions.¹⁷ We reported that during such situations, the Department of Defense may be responding to other events and its capacity to assist ASPR's response to a public

¹⁷ GAO-19-592.

health emergency may be limited. Therefore, we recommended that ASPR develop a strategy to demonstrate how the agency can provide a public health and medical services response if the Department of Defense's capacity to respond is limited. ASPR agreed with this recommendation but has not yet taken action to implement it. Further, according to the National Response Framework, the unprecedented scale of recent disasters highlights the need for further progress to build resilient capabilities to respond to disasters of increasing frequency and magnitude.¹⁸ For example, at the time of this report, HHS is responding to the COVID-19 pandemic nationwide and the National Oceanic and Atmospheric Administration has predicted that the 2020 Atlantic hurricane season will be more active than usual.¹⁹

- *Types of responders needed to care for at-risk individuals.* ASPR did not consider the responder types needed to care for at-risk individuals, such as children, the elderly, pregnant women, or individuals with chronic health conditions when developing the workforce target.²⁰ ASPR officials stated that this is not needed because NDMS responders provide medical stabilization to patients and move the patients to another facility for care, if required.²¹ However, the agency's fiscal year 2020 budget justification stated that ASPR had identified existing shortfalls in pediatric care during disasters, including trauma and critical care provided by NDMS. Our prior work in this area also showed that at-risk individuals were a key population requiring medical care during the 2017 hurricanes.²² Further, ASPR is required to take steps to ensure that NDMS includes an appropriate specialized and focused range of responder capabilities, which take into account the needs of at-risk individuals during a public health emergency.²³
- *Number of U.S. Public Health Service Commissioned Corps officers available to provide medical and public health care.* ASPR did not consider the U.S. Public Health Service Commissioned Corps officers or their capabilities when developing the NDMS workforce target, although these officers are available to assist with emergencies and disasters.²⁴ As a result, ASPR's NDMS workforce target may be too high or low (or targeting the wrong positions), depending on the number and type of officers able to provide medical and public health care. While commenting on a draft of this report, ASPR officials stated that Commissioned Corps officers primarily

¹⁸ Department of Homeland Security, *National Response Framework*, Fourth Edition (Washington, D.C.: Oct. 28, 2019).

¹⁹ National Oceanic and Atmospheric Administration, *Busy Atlantic hurricane season predicted for 2020*, accessed May 21, 2020, <https://www.noaa.gov/media-release/busy-atlantic-hurricane-season-predicted-for-2020>.

²⁰ Under 42 U.S.C. § 300hh-1(b)(4)(B), "the term 'at-risk individual' means children, pregnant women, senior citizens, and other individuals who have access or functional needs in the event of a public health emergency, as determined by the Secretary [of Health and Human Services]." The Secretary includes individuals with communication, chronic health, and behavioral health needs, among others, in the definition of at-risk individuals during an emergency or disaster.

²¹ While not specific to the workforce target, ASPR officials stated that they have in the last year given consideration to at-risk populations by, for example, working with organizations that take care of these populations, using subject matter experts for training on Acute Respiratory Infections in these population, and specific to children, working with the International Pediatric Association.

²² See GAO-19-592 and GAO, *Disaster Assistance: FEMA Action Needed to Better Support Individuals Who Are Older or Have Disabilities*, GAO-19-318 (Washington, D.C.: May 14, 2019).

²³ See 42 U.S.C. § 300hh-11(a)(3)(C).

²⁴ See Appendix I for more information on the U.S. Public Health Service Commissioned Corps officers available to assist during a federal emergency or disaster.

serve in administrative roles when deployed or, at best, support basic medical care. However, in recent years, Commissioned Corps officers have played an important response role. For example, the U.S. Public Health Service Commissioned Corps provided assistance during the 2017 hurricanes public health and medical services response by providing support such as managing evacuated patients. Additionally, during the ongoing COVID-19 pandemic, the Assistant Secretary for Preparedness and Response stated that the U.S. Public Health Service Commissioned Corps has been an important asset during the response.²⁵ According to U.S. Public Health Service officials, Commissioned Corps officers have assisted with the return of American citizens from China and Japan, airport screenings to monitor the health of travelers, and providing clinical care surge capacity in nursing facilities and field hospitals, among other COVID-19 response activities. Further, ASPR officials told us they may rely on the U.S. Public Health Service Commissioned Corps' mental health team for the care of individuals with behavioral and mental health needs during a response, making it all the more important that they consider their capabilities.

Regarding the U.S. Public Health Service Commissioned Corps and its relationship to the NDMS workforce target, ASPR officials originally stated that the agency does not have assurance that U.S. Public Health Service Commissioned Corps officers will be able to deploy quickly. As we described in the above paragraph, ASPR officials later commented that Commissioned Corps officers mostly support administrative requirements. With respect to the other critical workforce factors we identified, ASPR officials acknowledged that the agency did not consider these factors when developing the NDMS workforce target, and officials could not provide detailed information as to why they were not considered. For example, beyond building in redundancy to allow for responder availability (e.g., a Disaster Medical Assistance Team deploys with 35 responders, so each team is assigned 85 positions), officials could not tell us how they reached the number of positions for each type of team. Officials stated that to develop the NDMS team structures in the spring of 2018, they used Concept of Operations for each NDMS team type, as well as the Federal Emergency Management Agency's pre-scripted mission assignments, but did not provide further detail on how they used these documents.²⁶ Our analysis of these documents found that the documents do not align, so it is unclear how they were considered or used to develop ASPR's NDMS workforce target. For example, the pre-scripted mission assignments referred to team names and team sizes that were not included in the Disaster Medical Assistance Team concept of operations, and vice versa.

²⁵ CQ Congressional Transcripts, *House Oversight and Reform Committee Holds Hearing on Coronavirus Preparedness and Response, Part 2*, accessed March 31, 2020, <https://plus.cq.com/doc/congressional-transcripts-5859788?2>.

²⁶ The Concept of Operations addresses the mission and role of each NDMS team, deployment configurations, the team structure, requirements for team employees, operations during steady states and active states, and expectations of a deployment environment. According to Federal Emergency Management Agency officials, pre-scripted mission assignments are created prior to an incident to expedite the processing of a mission assignment once it is required. These mission assignments are created for capabilities that involve known or frequently used resources for services, such as logistics, communications, health care, and public safety. The National Response Framework establishes a response structure to coordinate federal resources during emergencies and disasters. Department of Homeland Security, *National Response Framework, Fourth Edition* (Washington, D.C., October 2019).

Nevertheless, the draft version of the agency's forthcoming strategic plan we received in March 2020, identifies the aforementioned workforce factors as important for future consideration. For example, it states that the agency plans to review the NDMS program to identify gaps in specialty care skills, capacity, training, and readiness to respond to multiple, simultaneous events, and national-level public health emergencies. The draft plan also states that medical surge capacity may be further supported through improved alignment across multiple groups of health care professionals, including the U.S. Public Health Service Commissioned Corps. While the draft strategic plan does not mention the development of a revised NDMS workforce target, ASPR's acknowledgement that these are important factors to consider is an important step forward. However, ASPR still needs to finalize its strategic plan, take specific actions to implement its plans to review these three key factors, and then adjust its workforce target accordingly.

ASPR Has Not Developed Strategies to Fill Identified Gaps in Critical Skills to Achieve an NDMS Workforce Target

Without an NDMS workforce target that considers the critical skills and competencies that are needed to meet current and future programmatic results—such as a workforce capable of responding to (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders—ASPR risks having an NDMS responder workforce target that is inadequate. For example, one that is too low, is redundant of other responders and therefore could be too high, or has gaps, such as a workforce that is unable to effectively care for all individuals affected by a public health emergency, as occurred during ASPR's response to the 2017 hurricanes.

According to key principles of effective workforce planning, once an agency has identified the critical skills and competencies needed of its workforce, the agency should then develop strategies to address gaps in the number, skills, and competencies of its workforce. Although we believe ASPR still needs to adequately identify the critical skills and competencies needed and related gaps of its NDMS workforce, the agency is operating under a current NDMS workforce target of 6,290.

However, as of December 2019, ASPR was not close to this target—having 3,667 responders enrolled in NDMS—and we found the agency has not developed specific strategies to drive hiring and fill its NDMS workforce gaps to reach its target.

ASPR officials told us that their hiring plan consisted of prioritizing NDMS job postings by posting those of high-priority first rather than posting them all at once. ASPR officials also stated they planned to implement a direct-hire authority, enacted in February 2018, by hiring as many NDMS responders as possible to meet the NDMS workforce target.²⁷ According to

²⁷ ASPR has received two direct-hire authorities for NDMS. The first was enacted as part of the Bipartisan Budget Act of 2018, and ran from February 9, 2018 to November 5, 2018. Pub. L. No. 115-123, § 20803, 132 Stat. 64, 95. The second was enacted as part of the Pandemic and All-Hazards Preparedness and Advancing Innovation Act of 2019 and runs from June 24, 2019 to September 30, 2021. Pub. L. No. 116-22, § 301(a)(3), 133 Stat. 905, 932 (codified at 42 U.S.C. § 300hh-11(c)(4)).

the Office of Personnel Management's website, the purpose of a direct-hire authority is to expedite hiring by eliminating some of the steps required for federal hiring.²⁸

We found that there have been no other strategies or specific intermediate goals for hiring and filling gaps to achieve its current NDMS workforce target. For example, intermediate goals could include milestones detailing the number of responders the agency aims to hire per month, taking into account any hiring resource constraints in order to establish a realistic timeline for completing all hiring, as well as establish an indicator by which they can measure progress. The lack of more detailed strategies may have contributed to the slow hiring that ASPR is currently facing. For example, as of March 2020, some NDMS responders were still going through the hiring process more than 16 months after they received offers from job postings made under the direct-hire authority.

Neither ASPR officials nor officials from HHS's Staffing Recruitment Operations Center (the agency within HHS that conducts all hiring actions on behalf of ASPR) could tell us when hiring will be completed.²⁹ Further, when asked about a plan or strategy to drive hiring under a second direct-hire authority enacted in June 2019, ASPR officials stated that they had started a draft plan. However, they put a hold on further plan development until the hiring under the first direct-hire authority is completed. As of March 18, 2020, 163 of the 1,447 individuals who accepted job offers under this first direct-hire authority are still in the process of being hired, according to ASPR officials.

Further, we found that ASPR is using a 2-year term appointment to hire all of the 1,447 responders under the first direct-hire authority. Because of this decision, Staffing Recruitment Operations Center officials told us that these responders will further burden hiring efforts because they will need to undergo an additional human resources action 2 years after they are hired to renew their appointment for an additional 2-year term. According to the job posting, the term appointment lasts for 2 years and may be extended for another 2 years, for a total of 4 years. If ASPR still has a need for these responders, they will have to rehire for these positions after 4 years. If hired under an indefinite term appointment, as was previously used to hire NDMS responders, this would have allowed these responders to serve for an indefinite amount of time. While officials stated that they will use an indefinite term position for hires under the second direct-hire authority, neither Staffing Recruitment Operations Center nor ASPR officials could tell us how they made the decision to use a 2-year term appointment for the first direct-hire authority. Officials from both agencies stated that the decision came from the other agency, further exemplifying a lack of strategies.

²⁸ Office of Personnel Management, *Hiring Information Direct Hire Authority Fact Sheet*, accessed April 3, 2020, <https://www.opm.gov/policy-data-oversight/hiring-information/direct-hire-authority/#url=Fact-Sheet>.

²⁹ Staffing Recruitment Operations Center officials stated that the center is one of nine human resource centers within HHS, which provides human resources services to HHS agencies that do not have a human resource center, including ASPR.

ASPR DOES NOT HAVE ASSURANCES IT IS EFFECTIVELY TRAINING RESPONDERS

ASPR Requires Web- Based Training and Also Offers In-Person Training, Which It Considers Most Beneficial, but Also More Costly to Provide

In the draft strategic plan provided to us, ASPR states that the agency wants to develop and launch a program to actively recruit medical professionals into NDMS, though there are no specifics included in the plan on how this will be achieved. It will be important for ASPR to develop specific plans. Without strategies to fill gaps to achieve an NDMS workforce target, ASPR continues to risk being unable to provide adequate numbers and types of NDMS responders to effectively respond to public health emergencies. It also risks not being able to take full advantage of the direct-hire authority that expires in September 2021.

ASPR requires NDMS responders to take introductory web-based training courses to be eligible for deployment. It also offers in-person training, which ASPR officials state is most beneficial for deployment preparedness but also more costly to provide. However, the agency does not sufficiently evaluate the quality or effectiveness of its training in preparing responders. Further, ASPR does not have a process or approach for establishing priorities among its in-person training courses.

ASPR requires NDMS responders to take introductory web-based training courses to be eligible for deployment. Specifically, ASPR requires responders to complete seven web-based training courses that are specific to preparedness to be eligible for deployment.³⁰ Many of these courses are required once in an NDMS responder's career. ASPR officials stated that these mandatory courses are intended to be a simple introduction to the topic areas, and the web-based aspect allows them to require these courses without incurring a large cost to the agency.

In recent years, ASPR has increased the number of mandatory courses specific to preparedness. For example, in fiscal year 2019, ASPR added five web-based video courses, many of which ASPR added per an identified need for more training specific to an infectious disease response, according to officials. In addition, based on a draft catalog of NDMS training courses for fiscal years 2020-2024, the agency plans to add an additional five courses, many of which are web-based courses provided by the Federal Emergency Management Agency, but as of March 2020, ASPR officials did not know when they would implement this training. See Table 3 for a description of the seven preparedness-related mandatory training courses, as well as the additional five that ASPR plans to add, including the frequency they are required to be taken.

In addition to the required web-based courses, ASPR also provides in- person training courses. ASPR officials told us that the agency's in- person training courses are the most beneficial, but they cannot require or offer as many in-person training courses as they would

³⁰ In addition to these seven, NDMS responders must also take five other mandatory courses that are general courses required by HHS: 1) Cybersecurity Training, 2) Ethics for Special Government Employees, 3) Ethics for OGE-450 Filers, 4) HHS Travel Charge Card, and 5) Sexual Harassment Prevention for Employees. Additionally, certain NDMS responders involved in patient movement must take a just-in-time refresher course on HHS's Joint Patient Assessment and Tracking System—a patient evacuation tracking system—as needed.

like, due to budget constraints and the cost of in-person courses relative to the web-based mandatory courses. Officials stated that in-person courses are most beneficial since they are more detailed than web-based courses and allow responders to more fully understand topics important for deployment. For example, ASPR brings responders together to be taught by a live instructor, and in some courses, practice using response equipment. Further, some of the courses are exercise-based so responders can practice their role in a simulated real-world scenario.

However, these courses are more expensive to offer. ASPR officials explained, for example, that for in-person training, ASPR compensates the instructors and responders for the time they are participating in the training, as well as pays the travel costs of the responders to the training site, such as flights and hotel costs. See appendix III for the 22 NDMS in-person training courses and their description, as well as those offered in fiscal year 2019.

ASPR Does Not Sufficiently Evaluate Its Training's Effectiveness in Preparing Responders

Our review of ASPR documentation shows that in fiscal year 2019, ASPR provided at least one offering of 14 of the 22 in-person training courses listed in its training catalog. For example, in fiscal year 2019, ASPR offered six Disaster Medical Assistance Team 101 trainings, each designed to provide up to 42 responders hands-on experience for delivering care to a diverse group of patients in a severe environment, including the appropriate use of equipment and supplies, among other topics. ASPR also offered 20 Isolation, Simulation, Quarantine trainings, each designed to teach up to 20 responders how to safely care for patients with highly hazardous communicable diseases in both health care and more austere environments, implement controls to curb the spread of disease, and contain accidental exposure to contamination, among other topics.

We found that ASPR does not sufficiently evaluate the quality or effectiveness of its training in preparing NDMS responders. This is because the agency lacks a process focused on evaluating both its web-based and in-person training. Instead, ASPR's process is to send an email with a link to a survey to responders who participate in the in-person training or those who deploy to real-world events, which would include those who received the required web-based training. The survey is optional (See Table 4 for the four standard questions).

However, the survey does not directly ask about the quality or effectiveness of the training. This approach is inconsistent with GAO-identified key practices for evaluating training, which include using measures of (1) training participants' reaction to, and satisfaction with, the training program and (2) changes in participants' knowledge, skills, abilities, and on-the-job behavior.³¹

³¹ GAO-04-546G.

Table 3. National Disaster Medical System (NDMS) preparedness-related mandatory training web-based courses

Training course	Fiscal year added	Course description	Frequency of required course completion
Psychological First Aid Training	2017	Introduces the concepts of Psychological First Aid and workforce resilience and prepares personnel to provide compassionate care and emotional support during emergencies and disasters.	Every 3 years
Safety 101 Training	2018	Provides initial safety training generally applicable to all responders to meet Department of Labor Occupational Safety and Health Administration requirements and enhance deployment safety.	Once in a responder's career
Pathogens of Concern	2019	Provides NDMS responders information about the characteristics of infectious diseases, specific pathogens and the diseases they cause, as well as how to recognize the signs and symptoms of disease to determine appropriate protection measures.	Once in a responder's career
Personal Protective Equipment Donning and Doffing	2019	Introduces the process of safely donning and doffing level C personal protective equipment providing chemical and biological protections to minimize exposure to hazards while providing care and support during disasters and public health emergencies. ^a	Once in a responder's career
Personal Protective Equipment Selection, Regulations, and Limitations	2019	Trains responders to identify and utilize different types of personal protective equipment and respirators while following federal regulations, as well as how to recognize possible limitations of use.	Once in a responder's career
Strategic National Stockpile Overview	2019	Provides a look at available resources, supplies, and equipment for emergency logistics and planning purposes.	Once in a responder's career

Notes: ^aLevel C protection is used when the type and concentration of an airborne substance is known, the criteria for using air-purifying respirators has been met, and skin and eye exposure is unlikely. ^bThe Incident Command System is the organizational management system designed to enable effective and efficient domestic incident management by integrating a combination of facilities, equipment, personnel, procedures, and communications operating within a common organizational structure. ^cThe National Incident Management System is the comprehensive approach guiding the whole community—all levels of government, nongovernmental organizations, and the private sector—to work together seamlessly to prevent, protect against, mitigate, respond to, and recover from the effects of incidents. ^dThe National Response Framework is an all-hazards response structure to coordinate federal resources during emergencies and disasters. It divides the federal response into 15 emergency support functional areas that are most frequently needed during a national response.

According to ASPR officials, although the survey is not specific to training, ASPR still receives feedback about the training courses through that survey, so they do not feel that they are missing any information from using this format to evaluate training. However, reliance on this process does not allow ASPR to understand training participants’ reaction to, and satisfaction with, the training, or whether responders’ knowledge, skills, and abilities or on-the-job behavior are affected if they deploy having received training. For example, it does not allow ASPR to understand whether the Disaster Medical Assistance Team 101 training course has an effect on responders’ ability to effectively provide care during a response. According to the NDMS training catalog, objectives of the Disaster Medical Assistance Team 101 course include that students have learned to use equipment and supplies in accordance with manufacturer instructions, and that those in clinical care positions have learned how to provide medical care to a diverse group of patients, including individuals with special health care needs, in a disaster setting. Effective evaluation questions could include those that specifically ask participants about these objectives and if they felt the objectives were met. For example,

- Did training participants feel that they sufficiently learned how to use the equipment and supplies in preparation for a real event?
- To what extent do training participants feel confident that they can apply the information they learned regarding use of equipment and supplies in a disaster setting, or teach it to others?

Table 4. Survey questions used to evaluate National Disaster Medical System in-person training

Survey question
1. Identify an issue or observation that requires corrective action(s). This should be a simple problem statement of 1 - 2 sentences in length.
2. Describe the issue or observation in detail. What was expected, but did or did not occur? Include the effect, positive or negative, and the consequence that actions had on the situation. Provide specific information that can be used for follow-up (dates, times, location, names, temporary fix, etc.).
3. What action(s) would you recommend to correct/resolve the issue or observation?
4. Submit positive feedback here.

Source: Office of the Assistant Secretary for Preparedness and Response National Disaster Medical System Responder Survey. | GAO-20-525.

Additionally, by relying on survey feedback once deployed to receive any information on the effectiveness of required web-based courses, ASPR does not know if they are effective until after the fact, which can potentially put responders and others at risk. For example, ASPR does not know if its required web-based course on donning and doffing personal protective equipment is effective until responders have deployed. At that point, if the training was not effective, the responder could have potentially exposed themselves and others to hazards, especially during a response to an infectious disease, chemical, or biological threat.

Our prior work has shown that a balanced, multilevel approach to evaluating training and development efforts is most appropriate, and that not all training and development programs

require, or are suitable for, higher levels of evaluation.¹ We acknowledge that higher levels of evaluation can be challenging to conduct because of the difficulty and costs associated with data collection and the complexity in directly linking training and development programs to improved individual and organizational performance. We have reported that factors to consider when deciding the appropriate level of evaluation include estimated costs of the training effort, size of the training audience, management interest, program visibility, and the anticipated “life span” of the effort. ASPR should consider these factors in developing a process that specifically evaluates the web-based and in-person training provided to NDMS responders. Using GAO-identified key practices for evaluating training could help ASPR know the extent to which its training is effective in preparing responders for deployment, including keeping them and others safe during a public health emergency. A process that specifically evaluates the training can also help determine whether the web-based or in-person training courses need to be improved, or whether any of the in-person training courses are so effective that they should be required.

ASPR Does Not Sufficiently Identify Priorities among Its In-Person Training Courses

Similarly, this information will allow ASPR to assess the relative effectiveness of in-person training courses, which is important when planning which of these training courses to offer each year.

We also found that ASPR does not sufficiently prioritize its in-person training. Specifically, ASPR has not sufficiently identified priorities among its in-person training courses that take into account its aforementioned resource constraints to provide this training, because the agency lacks a process or approach for prioritizing its training.

GAO-identified key practices for planning training state that an agency should prioritize training around funding so that the agency can address its most important training needs first.² Further, effective strategic workforce planning means that agency officials should develop training that they can implement with the resources that can be reasonably expected to be available, and be aligned to eliminate gaps and improve the contribution of critical skills and competencies needed for mission success.³

Because ASPR officials have no process or approach for prioritizing the in-person training, we found that ASPR officials could not provide information on how they chose the

¹ See GAO-04-546G. We reported that one commonly recognized four-level model for evaluating training and development efforts is a model conceived by Donald L. Kirkpatrick (author of *Evaluating Training Programs: The Four Levels*). In this model, the first level measures the training participants’ reaction to, and satisfaction with, the training program or planned actions to use new or enhanced competencies. The second level measures the extent to which learning has occurred because of the training effort. The third level measures the application of this learning to the work environment through changes in behavior that trainees exhibit on the job because of the training or development program. The fourth level measures the effect of the training program on the agency’s program or organizational results. The fourth level is sometimes split into two levels with the fifth level representing a comparison of costs and benefits quantified in dollars.

² A key tool to aid this prioritization is an annual training plan that targets developmental areas of greatest need and that outlines the most cost-effective training approaches to address those needs. We have also reported that if training is identified as a solution to improve performance, agencies should compare various training strategies by weighing their estimated costs and anticipated benefits. GAO-04-546G.

³ GAO-04-39.

14 in-person training courses the agency offered in fiscal year 2019, such as whether they prioritized any identified skill or competency gaps when selecting these courses. Further, ASPR officials could not provide documentation to support changes the agency made to training originally scheduled for fiscal year 2019. For example, ASPR documentation indicated that ASPR initially planned to offer an exercise-based Disaster Medical Assistance Team 201 course several times in fiscal year 2019 but did not end up offering the course at all. When asked about this change, ASPR officials attributed to its NDMS training budget. However, officials could not provide documentation showing that (1) their plans for the NDMS training the agency would offer in fiscal year 2019 had taken into account budget constraints, or (2) that the budget had changed subsequent to their plan development. As a result, it is difficult to know if the decision to drop the exercise-based Disaster Medical Assistance Team 201 course was due to budget constraints or due to poor planning, such as the agency not accounting for those constraints when originally determining which courses to offer.

CONCLUSION

A process or approach for identifying priorities among its in-person training courses while taking into account budget constraints, will help ASPR ensure that it is maximizing its available training resources, by providing the training responders need the most for effective deployment during a public health emergency.

The seriousness of recent natural disasters and the COVID-19 pandemic illustrate the importance of having a skilled workforce to respond to public health crises. However, our past work and current review of ASPR's workforce planning and training raise concerns about its efforts to prepare NDMS responders to assist during public health emergencies.

Specifically, ASPR experienced a shortage of NDMS responders to assist with the federal public health and medical response to the 2017 hurricanes. Since that time, the agency has not followed key strategic workforce planning principles to effectively address this response shortfall and prepare for future responses, including natural disasters of increased frequency and magnitude, which are predicted to occur. Until ASPR develops an NDMS workforce target that aligns with agency-wide goals and objectives, it risks being unable to fulfill its role as the lead agency for public health emergencies, which includes the ability to sufficiently enhance medical surge capacity during a response. In addition, until ASPR develops an NDMS workforce target that considers the critical skills and competencies needed to meet current and future programmatic results—such as a workforce capable of responding to (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders—ASPR risks having an NDMS responder workforce target that is inadequate.

Furthermore, ASPR has faced slow hiring and has not developed specific strategies to help drive hiring and address workforce gaps. Until ASPR develops strategies to fill gaps to achieve a workforce target, the agency continues to risk being unable to provide adequate numbers and types of NDMS responders to effectively respond to public health emergencies. It also risks not being able to take full advantage of the direct-hire authority that expires in September 2021 that is specifically designed to facilitate hiring.

Finally, ASPR does not have a process to collect information that would allow it to evaluate the effectiveness of the individual courses it offers in its training program nor a process to identify priorities among its in-person training courses. Such processes will help ASPR ensure that it is maximizing its available training resources to provide training most beneficial for effective deployment, including training to keep responders and others safe during a public health emergency.

RECOMMENDATIONS

We are making the following five recommendations to the Assistant Secretary for Preparedness and Response:

1. ASPR should develop an NDMS responder workforce target that aligns with the goals and objectives in ASPR's forthcoming strategic plan. (Recommendation 1)
2. ASPR should develop an NDMS responder workforce target that accounts for the critical skills and competencies that are needed to meet current and future programmatic results, such as a workforce target that considers (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders. (Recommendation 2)
3. ASPR should develop strategies to fill gaps to achieve its revised workforce target. (Recommendation 3)
4. ASPR should develop a process to evaluate the web-based and in-person training provided to NDMS responders using GAO-identified key practices for evaluating training. (Recommendation 4)
5. ASPR should develop a process or approach to prioritize various in-person training needs for its NDMS responders while taking into account budget constraints. (Recommendation 5)

AGENCY COMMENTS AND OUR EVALUATION

We provided a draft of this report for advance review and comment to HHS. HHS provided written comments, which we have reprinted in appendix IV. HHS concurred with our five recommendations and generally plans to take action.

Although HHS concurred with our five recommendations, the agency expressed concern about our references to the COVID-19 response in the draft report. Specifically, HHS noted that a pandemic response is outside the primary scope of NDMS—as its responders should be assisting the response through their civilian jobs, such as through working in hospitals—and for that reason COVID-19 pandemic planning did not include NDMS. While HHS states that it did not include NDMS in its COVID-19 planning, as we also state in our report, the agency has deployed more than 1,200 NDMS responders to assist in the COVID-19 response. Also in its comments, HHS stated that any assessment of NDMS in the ongoing response would be premature. Our review did not assess NDMS's response to COVID-19, rather we assessed

ASPR's workforce planning more generally for all-hazards events. We clarified this in the report.

HHS also commented on our concerns with HHS's evaluation of the training provided to NDMS responders. Specifically, the agency stated that we did not ground, in context or examples, our assertion that responders may be at risk since ASPR does not receive feedback on training until after deployment. We stand by our statement that there is the potential for this risk to occur given that HHS does not collect specific feedback on its trainings' quality or effectiveness and does not collect any feedback on mandatory training until after a responder has been deployed. As discussed in the report, an example is the mandatory web- based training on donning and doffing personal protective equipment.

ASPR does not know if this training course is effective until responders have deployed. At that point, if the training was not effective, responders could have potentially exposed themselves and others to hazards, especially during a response to an infectious disease, chemical, or biological threat.

HHS also provided technical comments, which we incorporated as appropriate.

Mary Denigan-Macauley
Director, Health Care

APPENDIX I: U.S. PUBLIC HEALTH SERVICE COMMISSIONED CORPS OFFICERS AND THE READY RESERVE CORPS

Current Number of Officers Who Provide Medical Care to Humans during a Response

The U.S. Public Health Service, an agency under the Department of Health and Human Services (HHS), comprises Commissioned Corps officers who are available to assist with emergencies and disasters.⁴ Commissioned Corps officers' duty stations are typically within the federal government, including agencies within HHS such as the Centers for Disease Control and Prevention, Food and Drug Administration, and National Institutes of Health, but these officers can be temporarily assigned to HHS's Office of the Assistant Secretary for Preparedness and Response to assist with a federal response.

There are a number of types of Commissioned Corps officers, including those who are deployed to provide medical care to humans during a response and fall within four professional categories—dental officer, health services officer, medical officer, and nurse officer.⁵ As of October 4, 2019, the U.S. Public Health Service had 2,127 of these types of officers available to assist with emergencies and disasters (See Table 5).

⁴ Commissioned Corps officers may be deployed to respond to an urgent or emergency public health care need arising from (1) a national emergency declared by the President under the National Emergencies Act; (2) an emergency or major disaster declared by the President under the Robert T. Stafford Disaster Relief and Emergency Assistance Act; (3) a public health emergency declared by the Secretary of Health and Human Services under the Public Health Service Act; or (4) any emergency that is appropriate for deployment, as determined by the Secretary of Health and Human Services. See 42 U.S.C. §§ 204a(a)(5) and 215(e).

⁵ There are 11 professional categories for Commissioned Corps officers: physicians, dentists, clinical and rehabilitation therapists, dietitians, engineers, environmental health, health service, nurses, pharmacists,

Table 5. U.S. Public Health Service Commissioned Corp Officers available to provide medical care to humans during a response, by provider type

Professional category	Number of responders	Percent of total number of responders
Dental officer	141	6.6
Health Services officer	156	7.3
Medical officer	460	21.6
Nurse officer	1,370	64.4
Total	2,127	99.9 ^a

Source: GAO analysis of U.S. Public Health Service data as of Oct. 4, 2019. | GAO-20-525.

Note: ^aThe total percentage does not sum to 100 due to rounding.

Table 6. U.S. Public Health Service Commissioned Corps Officers available to provide medical care to humans during a response, by deployment team

Team name	Team description	Number of officers available to provide medical care to humans
Rapid Deployment Force	Health and medical services to support a Federal Medical Station. ^a	300
Capital Area Provider	Health and medical services to support national special security events in the national capital region.	96
Mental Health	Behavioral health services for impacted citizens and deployment teams.	29
Applied Public Health	Public health services to augment state and local public health departments.	39
Regional Incident Support	Incident support services focused on liaison and information management.	45
National Incident Support	Incident support services focused on assisting command and control.	16
Services Access	Assist impacted citizens and federal partners with access to follow-on services. ^b	63
Tier 3	Augment any of the above teams once deployed.	1,539
Total		2,127

Source: GAO analysis of U.S. Public Health Service data as of Oct. 4, 2019. | GAO-20-525.

Notes: ^aA Federal Medical Station is a Health and Human Services deployable health care facility that has a 3-day supply of medical and pharmaceutical resources to sustain from 50 to 250 patients who require medical services.

^bFollow-on services can range from providing support to health care institutions on the discharge planning process to connecting individuals affected by a disaster or emergency to services such as housing or home health care.

These officers are assigned to deployment teams that provide both direct and indirect health care services to humans. The deployment teams provide support ranging from providing medical services to connecting affected individuals with community services, such as home health care. See Table 6 for the number of U.S. Public Health Service Commission Corps officers available to provide medical care to humans during a response, by deployment team.

science and research health professions, and veterinary medicine. As of September 9, 2019, these officers totaled to approximately 6,200 Commissioned Corps. According to Public Health Service officials, as of March 2020, ASPR had only requested four of these 11 professional categories to help provide medical care to humans during a response to a disaster or emergency—dental, health services, medical, and nurse officers. Medical officers are physicians. Health services officers include allied clinical care providers, such as physician assistants and optometrists, and those that serve in other roles, such as health information managers and public health educators and administrators.

PLANS FOR A READY RESERVE CORPS

To augment capacity, the U.S. Public Health Service is in the process of implementing a Ready Reserve Corps, but plans are still in development.⁶ The Ready Reserve Corps would consist of intermittent employees who could be called up as needed. Implementing a Ready Reserve is part of a broader plan to modernize the U.S. Public Health Service Commissioned Corps announced by the Assistant Secretary for Health in March 2018. A contractor hired to assist with the modernization effort assessed the agency and concluded in April 2019 that, among other things, establishing a Ready Reserve Corps will give the U.S. Public Health Service Commissioned Corps the needed bandwidth to meet demand for its services. The contractor stated that the demand for services is likely to increase in the future based on multiple demand signals (e.g., natural disasters, biological pathogens, the opioid epidemic and suicide clusters, and international and immigrant-related situations).

In September 2019, the U.S. Public Health Service tasked the contractor with developing a plan by June 10, 2020, to establish the Ready Reserve Corps, including an organization infrastructure design plan and recruitment strategy. It also included the development of a training plan applicable to Commissioned Corps Officers.

U.S. Public Health Service officials we spoke with agreed that the introduction of a Ready Reserve Corps would dramatically help their ability and capacity to respond to emergencies and disasters, especially given the rise in demand on the agency. According to these officials, the number of U.S. Public Health Service Commissioned Corps deployments has increased 44 percent over 6 years—from calendar year 2013-2018—and officials expect demand to continue to grow. Ready Reserve Corps officers would be deployed or backfill positions of deployed U.S. Public Health Service Commissioned Corps officers.

U.S. Public Health Service officials stated that there is a target of commissioning 100 Ready Reserve Corps officers in fiscal year 2021, which was set based upon fiscal constraints and force management planning factors. According to officials, since the vast majority of the work in the first year of establishing a Ready Reserves Corps will be dedicated to establishing the policies, procedures, information technology, and management infrastructure necessary to recruit, organize, train, and manage a ready reserve component, a conservative target was deemed most prudent. Officials stated that 50 percent of their goal of 100 Ready Reserve Corps officers will be targeted toward retaining already trained officers with significant clinical experience who otherwise would separate completely from the service.

⁶ The Ready Reserve Corps was established in 2010 by the Patient Protection and Affordable Care Act to have additional personnel available to assist the U.S. Public Health Service Commissioned Corps with routine and emergency missions. Pub. L. No. 111-148, § 5210, 124 Stat. 119, 614-15 (2010) (codified as amended at 42 U.S.C. § 204). The CARES Act amends federal law to allow members of the Ready Reserve Corps to receive certain compensation and benefits for their service. See Pub. L. No. 116-136, § 3214(d) 134 Stat. 281, 373 (2020) (to be codified at 42 U.S.C. § 213a).

APPENDIX II: NATIONAL DISASTER MEDICAL SYSTEM TEAM STRUCTURES

The Office of the Assistant Secretary for Preparedness and Response (ASPR) enrolls responders into its National Disaster Medical System (NDMS). Once enrolled, ASPR can deploy these responders to assist with the federal public health and medical response during a public health emergency. There are five types of NDMS responder teams. Two of these types,

Table 7. Team structures for each national disaster medical system team

the Disaster Medical Assistance Team and the Trauma and Critical Care Team, focus on providing public health and medical care to humans during a response. The National Veterinary Response Team provides veterinary care, while the Victim Identification Team and Disaster Mortuary Operational Response Team collect information on victims and support local mortuary services during a response, respectively. In March 2018, ASPR developed team structures for each NDMS team type, which include position types and numbers of responders in each position. See Table 7 for the team structures of each of the five types of NDMS teams.

**APPENDIX III: NATIONAL DISASTER MEDICAL SYSTEM OPTIONAL
TRAINING COURSES FOR RESPONDERS**

The Office of the Assistant Secretary for Preparedness and Response (ASPR) enrolls responders into the National Disaster Medical System (NDMS). Once enrolled, ASPR can deploy these responders to provide medical care, evacuate patients, and provide veterinary services, among other supports.⁷ To prepare these responders for deployment, ASPR offers optional, in-person training throughout the year. This training may be applicable to all responders, or specific to responders on certain of the five types of NDMS teams. Table 8 summarizes the 22 optional training courses that may be available to NDMS responders, though not all courses are available each year.

**Table 8. Optional training courses for National Disaster
Medical System (NDMS) responders**

Course name	Course description	Course capacity (max participants per course offering)	Number of course offerings in fiscal year 2019
Aeromedical Evacuation Team	Develop the skills required of NDMS responders as members of an aeromedical evacuation team expected to deliver care in flight.	25	10
Aeromedical Evacuation Team Critical Care	Develop the skills required of NDMS responders on an aeromedical evacuation critical care team who are expected to deliver critical care in flight.	18	5
Critical Care Air Transport Team Advanced	Develop skills related to the clinical care of the critically ill and injured patients in flight.	18	1
Critical Care Air Transport Team Initial	Teach and test operational concepts, flight and altitude physiology, and critical care knowledge as it applies to air and ground transport of a critically ill or injured patient.	18	7

⁷ Under 42 U.S.C. § 300hh-11, NDMS may be activated to provide health services, health- related social services, other appropriate human services, and appropriate auxiliary services to respond to the needs of victims of a public health emergency. ASPR may also activate NDMS in a location that is at-risk of an emergency.

Course name	Course description	Course capacity (max participants per course offering)	Number of course offerings in fiscal year 2019
Disaster Medical Assistance Team 101	Develop and improve upon the skills required of NDMS Disaster Medical Assistance Team responders to deliver care in a severe environment and familiarize new or not recently deployed personnel on general principles of NDMS deployments.	42	6
Disaster Medical Assistance Team 201 Exercise	Prepare NDMS Disaster Medical Assistance Teams for short-notice disaster relief deployments. The training involves the reporting, mobilization, and demobilization activities that would occur during an actual deployment.	No course capacity maximum indicated	0
Disaster Mortuary Operational Response Teams 101	Allow mortuary specialists—one of the positions on the NDMS Disaster Mortuary Operational Response Teams who identify victims and support local mortuary services—to prepare, train, and enhance the processes, procedures, and practices used during Disaster Mortuary Operational Response Team missions.	100	0
Disaster Mortuary Operational Response Teams 201	Prepare NDMS Disaster Mortuary Operational Response Teams for short-notice disaster relief deployments. The training involves the reporting, mobilization, and demobilization activities that would occur during an actual deployment.	80	
Electronic Medical Records	Update the knowledge, skills, and response capabilities of emergency medical records users in the revised deployment and utilization of the new emergency medical records software.	36	
Highly Infectious Disease Patient Transport	Address the transportation of highly infectious patients to appropriate facilities such as assessment or isolation centers.	No course capacity maximum indicated	
Isolation, Simulation, Quarantine	Provide the knowledge, skills, and abilities to ensure that competencies in the areas of situational awareness, preparedness and planning, infection prevention and control, and crisis and risk communication are met.	20	
Joint Patient Assessment and Tracking System	Improve the knowledge, skills, and response capabilities of responders in the deployment and utilization of the Joint Patient Assessment and Tracking System (a patient evacuation tracking system) software.	36	
Joint Patient Assessment and Tracking System Exercise: Supporting Department of Defense and Veterans Affairs Federal Coordinating Center	Support Federal Coordinating Center exercises conducted by the Departments of Defense and Veterans Affairs with a two-person Joint Patient Assessment and Tracking System Team. ^a These exercises are controlled and scenario-driven trainings for federal responders.	2	

Table 8. (Continued)

Course name	Course description	Course capacity (max participants per course offering)	Number of course offerings in fiscal year 2019
Regional Equipment Familiarization	Prepare responders enrolled in NDMS Disaster Medical Assistance Teams for the challenges of disaster care by supporting familiarization with field equipment.	40	Regional Equipment Familiarization
Logistics Specialist 101	Utilize a combination of classroom and hands-on training to familiarize logistical personnel with equipment used during actual deployments.	50	
NDMS/Department of Defense Outbreak Response Course	Prepare responders to support operations that may involve infectious diseases with high infectivity, morbidity, and mortality.	12	
National Veterinary Response Team Working Animal	Prepare NDMS National Veterinary Response Team responders to properly handle and provide medical support to working animals used in post-disaster environment, public health emergency, or planned national security event.	55	
Trauma Critical Care Team 101	Allow responders enrolled in NDMS Trauma and Critical Care Teams to deliver the highest level of trauma and critical care to victims of disasters in accordance with current clinical standards and NDMS guidelines.	48	
Team Leadership	Improve the knowledge, skills, and response capabilities of NDMS Team Commanders and Deputy Team Commanders to enhance their leadership capabilities. ^b	142	
Safety Specialist 101	Qualify Safety and Occupational Health Specialists—a responder position on all of the NDMS teams except the Victim Identification Team—to perform pre-deployment health and safety activities.	14	
Victim Identification Center 101	Allow the Victim Identification Response team and all 10 NDMS Disaster Mortuary Operational Response Teams to train and prepare for the practice of ante mortem (before death) data collection used during disaster missions. ^c	35	
Trauma and Critical Care Team 201 Exercise	Prepare NDMS Trauma and Critical Care Teams for short-notice disaster relief deployments.	48	

Source: GAO summary of Office of the Assistant Secretary for Preparedness and Response NDMS training documentation. | GAO-20-525.

Notes:

^aFederal Coordinating Centers are activated to receive, triage, stage, track, and transport patients affected by a disaster or national emergency to a participating NDMS medical facility capable of providing the required care to manage the patient's condition.

^bEach NDMS team is led by a Team Leader and a Deputy Team Leader that constitute a team's Command Staff during steady state or day-to-day operations.

^cThe Victim Information Center is a location for local authorities and Disaster Mortuary Operational Response Team members to collect ante-mortem data, such as pictures, fingerprints, dental X-rays, and other medical records, to help identify the victim.

APPENDIX IV: COMMENTS FROM THE DEPARTMENT OF HEALTH AND HUMAN SERVICES

DEPARTMENT OF HEALTH & HUMAN SERVICES

OFFICE OF THE SECRETARY

Assistant Secretary for Legislation
Washington, DC 20201

May 28, 2020

Mary Demigan-Macaulay
Director, Health Care
U.S. Government Accountability Office
441 G Street NW
Washington, DC 20548

Dear Ms. Demigan-Macaulay:

Attached are comments on the U.S. Government Accountability Office's (GAO) report entitled, *"PUBLIC HEALTH PREPAREDNESS: HHS Should Take Actions to Ensure It Has an Adequate Number of Effectively Trained Emergency Responders"* (GAO-20-525).

The Department appreciates the opportunity to review this report prior to publication.

Sincerely,

Sarah C.
Arbes-S

Principal Deputy
Assistant Secretary
for Legislation

Sarah C. Arbes
Assistant Secretary for Legislation

Attachment

GENERAL COMMENTS FROM THE DEPARTMENT OF HEALTH & HUMAN SERVICES ON THE GOVERNMENT ACCOUNTABILITY OFFICE'S DRAFT REPORT ENTITLED -- PUBLIC HEALTH PREPAREDNESS: HHS SHOULD TAKE ACTIONS TO ENSURE IT HAS AN ADEQUATE NUMBER OF EFFECTIVELY TRAINED EMERGENCY RESPONDERS (GAO-20-525)

The U.S. Department of Health & Human Services (HHS) appreciates the opportunity from the Government Accountability Office (GAO) to review and comment on this draft report.

While this report refers to the COVID-19, it is important to note that GAO work on the National Disaster Medical System (NDMS) was well underway prior to the advent of the pandemic. Thus, we raise concerns about COVID-19 references throughout the report. Our chief concern is that pandemic response is outside the primary scope of the NDMS, as NDMS employees should be primarily working in their civilian jobs within the traditional healthcare system. The COVID-19 pandemic planning, therefore, did not include NDMS. The governing assumption was the federal response should not compromise the community healthcare capabilities. Furthermore, HHS remains in the middle of its pandemic response, thus any assessment of NDMS during this time is premature at best.

Secondly, HHS would like to address the GAO's concerns with the training regimen. GAO asserts that collecting feedback about training from providers whom are deployed potentially places them at risk. However, this assertion is made with no examples or grounding in context of the training delivered. Where there is opportunity to improve training, HHS will work diligently to incorporate best practices in the preparation of its NDMS workforce.

Going forward, HHS will work to develop a strategic documented workforce target that considers (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders to fill the gaps in workforce target.

Recommendation 1

ASPR should develop an NDMS responder workforce target that aligns with the goals and objectives in ASPR's forthcoming strategic plan.

HHS Response

HHS concurs with GAO's recommendation. ASPR will work to align all goals and objectives to the strategic plan.

Recommendation 2

ASPR should develop an NDMS responder workforce target that accounts for the critical skills and competencies that are needed to meet current and future programmatic results, such as a workforce target that considers (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders.

HHS Response

HHS concurs with GAO's recommendation. ASPR will work to develop a strategic documented workforce target that considers (1) a nationwide event or multiple concurrent events, (2) the needs of at-risk individuals, and (3) the availability of other medical responders. ASPR's ability to realize this workforce target will be subject to the availability of funding.

GENERAL COMMENTS FROM THE DEPARTMENT OF HEALTH & HUMAN SERVICES ON THE GOVERNMENT ACCOUNTABILITY OFFICE'S DRAFT REPORT ENTITLED -- PUBLIC HEALTH PREPAREDNESS: HHS SHOULD TAKE ACTIONS TO ENSURE IT HAS AN ADEQUATE NUMBER OF EFFECTIVELY TRAINED EMERGENCY RESPONDERS (GAO-20-525)

Recommendation 3

ASPR should develop strategies to fill gaps to achieve its revised workforce target.

HHS Response

HHS concurs with GAO's recommendation. This recommendation will be subject to the availability of funding.

Recommendation 4

ASPR should develop a process to evaluate the web-based and in-person training provided to NDMS responders using GAO-identified key practices for evaluating training.

HHS Response

HHS concurs with GAO's recommendation. ASPR will work to incorporate GAO-identified key practices into training evaluation.

Recommendation 5

ASPR should develop a process or approach to prioritize various in-person training needs for its NDMS responders while taking into account budget constraints.

HHS Response

HHS concurs with GAO's recommendation. ASPR will continue to prioritize in-person training for NDMS responders.

Chapter 550

PROSOPIS GENUS: POTENTIAL USES AND APPLICATIONS WITH SPECIAL REFERENCE TO PUBLIC HEALTH AND IN VETERINARY MEDICINE

ABSTRACT

This chapter provides a general overview of the main aspects related to the Fabaceae (Leguminosae) family, focusing on species of the genus *Prosopis* and covering their main aspects, such as nutritional characteristics, beneficial aspects in different social strata as well as their usage as food, traditional medicine and other uses. General information about their physiological and ecological aspects is provided, particularly regarding their role in maintaining the biodiversity of ecosystems. The enormous capability of *Prosopis* species to fix atmospheric nitrogen, retaining soil fertility, and their important contribution to soil remediation as also discussed. Furthermore, chemical aspects of the plant as well as the main secondary metabolites and their implications in the control of a large list of diseases are also discussed. This chapter focuses on the potential use of *Prosopis* species in human health and veterinary medicine. *Prosopis* species offer a wide range of uses and applications in different areas, such as a nutritional supplement, as feed

* Corresponding Author's Email: pedromdgives@yahoo.com.

for livestock, as a retainer of soil fertility and as an invaluable natural and sustainable medical source in both human and animal health.

INTRODUCTION

The extraordinary richness in plant biodiversity, associated with the soil microbiome, contributes to the stability of ecosystems all over the world (Trivedi et al., 2020). Against the background of a changing climate, most plant species living in different ecosystems are greatly affected, and their permanence under natural conditions mainly depends on their genetic capability for adaptation to such adverse conditions (Minorsky, 2002; Becklin et al., 2016). Leguminosae plants are one of the largest groups of plants in the world, with almost 18,000 species (Al-Tawaha et al., 2020); they are adapted to almost all terrestrial ecosystems and occur as trees, shrubs, vines and annual herbs (Vasconcelos et al., 2020). This group of plants is widely spread in many countries mainly in tropical and subtropical areas around the world (Sacheti and Al-Rawahy, 1998) and plays an important role because of its symbiotic system of atmospheric N₂ fixation through a bacteria-containing root nodule system (Schwember et al., 2019). Leguminous plants can be found in various habitats, where they provide a natural source of shade for humans and animals and are agricultural crops, either as a legume produced for human consumption, pasture, forage, or as silage for livestock and soil-enhancing green manure (Gutiérrez-Urbe et al., 2016).

The genus *Prosopis* is a group of plants belonging to the Leguminosae family and is also called “Fabaceae”, comprising 44 species (Burkart, 1976). It is widespread in arid and semi-arid regions around the world, including Central and North Africa, South and North America and the Caribbean region (Asaf et al., 2020). Species belonging to this group of plants have been considered in some countries to be invasive plants (Shackleton et al., 2015), threatening indigenous plant species and putting the biodiversity in some regions at risk (Muturi, 2009, Rejmánek and Richardson, 2013).

In some regions, this genus is highly valued because of its beneficial properties, whereas in other regions, it is considered an undesirable weed (Shackleton et al., 2014). Some studies have demonstrated that *Prosopis* species are necessary to achieve an environmental equilibrium, where plants of this group play an important role in erosion control and biodiversity support (Kumar-Prusty, 2009). *Prosopis* trees have been considered a valuable resource to reforest arid zones (de la Vega et al., 1996).

In many other countries, *Prosopis* species are highly appreciated and used as fast-growing ornamental trees in landscapes (Brown, 1991).

Other important uses for species of this genus are as a source of fuel for communities; they often are the major source of firewood and charcoal and a source of energy for refugee communities (Gianvenuti et al., 2018).

Tree species of this genus have also been used for bioethanol production (Sindhu and Gnanavel, 2016).

Prosopis species also serve as a valuable source of nutrients for wild animals since they contain protein, fibre and sugars (Ruiz-Nieto et al., 2020). These nutrients also play an important nutritional role in livestock feeding (Pasiiecznik et al., 2001; Santos et al., 2015).

Other *Prosopis* species, i.e., Mesquite, are used for human consumption, and many dishes made with this plant are prepared in Central American countries and include bread, syrup,

sweets and sweeteners, alcoholic beverages and a sort of coffee substitute (Gutteridge and Shelton, 1994). Additionally, in the culinary industry, the flour of *Prosopis* species is used because of its nutritive and bioactive properties in breadmaking (Gonzales-Barron et al., 2020).

Prosopis species contain various medicinal properties and are applied as natural remedies in the general health sector and in veterinary.

Recent studies exploring the metabolomics aspects of this interesting group of plants have identified molecules with the potential for the control of diseases either in humans or animals (Sharifi-Rad et al., 2019; Miri et al., 2020; Delgado-Núñez et al., 2020). A list of phytochemical compounds, such as alkaloids, tannins, phenolics, steroids, terpenes and flavonoids associated with medicinal properties, has recently been published (Ruiz-Nieto et al., 2020).

Figure 1. Diagram about some of the most frequent uses and applications of *Prosopis* species around the world.

Figure 1 shows the most beneficial characteristics of *Prosopis* species for humans. The circles represent every one of the potential uses of the plant with impact on a wide diversity of fields that benefit not only humans and animals, but also the larger environment.

Plants of this genus are considered valuable crops and are currently attracting increased interest from researchers on a global level. This chapter presents a general view of the most important aspects of the genus *Prosopis*, with special reference to its potential use in public health and veterinary medicine.

ADAPTABILITY OF *PROSOPIS* SPECIES TO ECOSYSTEMS

The genus *Prosopis* genus has an extraordinary capability for physiological adaptation to inhospitable ecosystems, and it is common to see species growing under severely adverse conditions, particularly in semiarid and arid climates of the Americas, Asia and Africa (Pasiecznik et al., 2004). *Prosopis* species can survive in different xeric environments, where, over time, some species have developed specific ecophysiological mechanisms to be able to survive under such hostile conditions (Carevic, 2014). Likewise, *Prosopis* species can synthesise chemical defense molecules with implication as nutraceuticals and phytopharmaceutical compounds (Persia et al., 2016), providing a range of competitive ecological advantages that allow them to widely self-establish in physiognomic territories, mainly under hydric deficit conditions (Passera, 2000). This group of plants can tolerate drought and adverse edaphic conditions such as salinity and alkalinity as well as having an extraordinary adaptation to herbivory. These are the main reasons why these plants have gained a dominant position in the woody vegetation of arid and semiarid zones of the Americas (Villagra, 2000; Meloni et al., 2004). Due to their abundance and ecological behaviour, *Prosopis* species play a crucial economical role, mainly in rural zones (Argaw, 2015). *Prosopis* species are also important in maintaining some ecosystem balance in cases of deforestation because of firewood gathering and charcoal production, where *Prosopis* facilitates natural reforestation by massive plant propagation, preserving its species and genetic features (Rivera et al., 2020). In South America, the relationship between *Prosopis* species and humans can be traced back to pre-Columbian ages, where these species constituted the main food for humans and animals (Roig, 1993). It can grow on sand dunes (Hennessy et al., 1985), ephemeral xero-riparian washes (Warren and Anderson, 1985), abandoned lakebeds and edges of lakes (Jarrel and Virginia, 1990) and river floodplains. Only under riparian conditions, *Prosopis* trees or “mesquite” trees grow to reach their maximum height, mainly in dense woodlands.

Mesquite is a Mexican tree whose name is derived from the Náhuatl native language (Mizquilt). The species grows in semi-desert zones with low rainfall and can be found in arid and semiarid regions in Southeast Sonora, the northern part of the Sinaloa, Chihuahua Mexican states and in other arid regions of Mexico (Rodríguez and Maldonado, 1996).

These trees grow better in the confluences of rivers and along the alluvial plains of large rivers with a low slope and along rivers that flow through wide valleys with no restrictions (Szaro, 1990). Mezquite woodlands (*Prosopis* spp.) in the United States of America have spread to southeastern Utah, southwestern Kansas, southern Texas and southeastern California. Historically, *Prosopis* trees have represented one of the most abundant riparian communities, but nowadays, they are reduced to a remnant state. This tree community is localised in high alluvial plains of 2 to 15 m above sea level. Inside riparian ecosystems, which historically covered several kilometres in width, they extended their territory along hundreds of kilometres in the lower parts of rivers (Ellsworth et al., 2018).

In other countries, different species of the genus *Prosopis* have been described. For instance, in Mexico, eleven mesquite species have been identified in almost all regions of the country, mainly in arid and semiarid regions. In Mexico, the following species of *Prosopis* have been identified: *P. odorata*, *P. glandulosa*, *P. velutina*, *P. articulate*, *P. tamaulipana*, *P.*

yaquiana, *P. mayana*, *P. vidaliana*, *P. laevigata*, *P. mezcalana* and *P. juliflora* (Palacios, 2006).

On the other hand, the density of the trees is important for the growth of *Prosopis* species. It should be considered that many decades ago, the woodland areas worldwide were considerably larger, whereas nowadays, they are reduced in size and composed of dense stands of trees that are younger and smaller compared to their potential size of 18 m in height and 1.5 m in stem diameter (Ansley et al., 1997). The woodland overstory is dominated by mesquite species, but the underground woodlands can support a diverse set of bushes, climbing plants and herbaceous plants (Ansley et al., 2010). Mesquite trees are characterised by high productivity due to the combination of a deep root system that extends almost to the riparian phreatic level and nitrogen-fixing symbiotic bacteria (Kulkarni and Nautiyal, 1999). Productivity is high, with abundant flower and fruit production, allowing colonisation by diverse and abundant animal species. For example, mesquite woodlands harbour one of the highest densities of reproductive chickens of any habitat (Boggie et al., 2017). Woodlands are continuously threatened by human activities such as groundwater pumping, surface water diversion, forest clearing and cutting trees for wood, as well as soil changes for livestock grazing (Felker, 1990). *Prosopis* species have also been considered a suitable plant to prevent soil erosion (Al-Assaf et al., 2020).

PHYTOCHEMISTRY AND BIOLOGICAL ACTIVITY OF THE GENUS *PROSOPIS*

As previously stated, *Prosopis* species are not only a crucial source of nutrients in the diet of humans, but are also traditionally used because of the medicinal properties (Luna-Nemecio, 2019; Gallegos, 2016; Dardón and Retana, 2017). Most of the medicinal uses were originally employed on an empirical basis. However, studies of the chemistry and metabolomics of *Prosopis* species have led to the identification of several secondary metabolites, resulting in a long list of chemical compounds used in different industrial sectors, including cosmetics, pharmaceuticals or medicines (Damasceno et al., 2020). In the last decades, some phytochemicals from *Prosopis* species of medicinal importance, including alkaloids and phenolic compounds such as flavonoids, terpenes, tannins and saponins, have been reported (Ibrahim et al., 2013). These findings contribute to the scientific search for other alternative curative tools against a range of pathogens and diseases. For example, *P. glandulosae* has antimicrobial activity against *Vibrio cholerae*, one of the most dangerous enteric pathogenic bacteria responsible for cholera; it has been estimated that each year, there are 1.3 to 4.0 million cases of cholera, with 21,000 to 143,000 deaths worldwide (FAO, 2019).

The chemical composition as well as the pharmacological activity of *P. juliflora* Swartz DC, which is one of the most abundantly spread species and one of the most studied ones, has recently been reported. Due to its high content of flavonoids, *P. juliflora* can be considered as an important natural anticancer source according to Odero et al. (2017). These authors also reported the presence of a compound called “mesquitol” (Figure 2) as a major compound in this species, associated with antioxidant activity. The presence of alkaloids (3.6%) in this plant supports its use as analgesic, antispasmodic and bactericidal compound (Ibrahim et al.,

2013; Dey et al., 2020). Quantitative analysis of this species revealed a 2.2% saponin content in *P. juliflora* leaves. In this regard, some authors have explored other medicinal properties of saponins, and particularly steroids have shown antimicrobial (Sobolewska et al., 2020), antiprotozoal (Henciya et al., 2017), cytotoxic and anticancer (Persia et al., 2020), molluscicidal (Ukande et al., 2019), antitumour and fungicidal (Sharifi-Rad et al., 2019), insecticidal and acaricidal activities (Brito-Mancero et al., 2019).

The phenolic compounds present in *P. juliflora* and *P. pallida* have been associated with nutraceutical and antioxidant properties (Suárez-Rebaza et al., 2019). The most important phenolic compounds found in *P. juliflora* belong to the following groups: flavonoids (quercetin, kaempferol, myricetin and isorhamnetin) and phenolic acids (gallic, coumaric, caffeic and chlorogenic). These compounds possess a synergistic effect with flavonoids and together achieve an enhanced effect as antioxidant and anticancer agents. Some chemical structures as well as the part of the plant used and their pharmacological properties are shown in Figure 2. The tannin concentration is generally low.

Some authors have stated that the consumption of plants containing such metabolites leads to a significant reduction in the risk of contracting some chronic diseases (Afrin et al., 2016). The consumption of plants of the genus *Prosopis* is therefore recommended to increase general health.

A wide range of biological applications of *Prosopis* species, particularly because of their pharmacological potential as well as the variety and abundance of phytochemical compounds, has been reported. Various bioactive substances with medicinal effects, including alkaloids (juliflorine, juliprosopine, prosoflorine, julisopropine, patulitrin and piperidine) as well as flavonoids (mesquitol) and tannins such as antraquinones and quinones have been reported for *P. juliflora* (Ukande et al., 2019). The activities described for these compounds varied from inhibition of acetylcholinesterase, blocking calcium channels, gas production inhibition during ruminal digestion, anti-lung cancer activity, antioxidant activity, inhibition of drug-resistant fungi, glial cell activation and inhibition of H⁺, K⁺ and ATPase of *Helicobacter pylori*. These findings could be useful when establishing the ethnopharmacological basis for *Prosopis* plant species for future phytochemical and pharmacological studies focusing on the treatment of several diseases of importance in public health. Similarly, other secondary metabolites have been identified in other *Prosopis* species; most of them correspond to a piperidine alkaloids known as “prosopinine” (isolated from *P. juliflora*), which has been used as a local anaesthetic, and “Prosopine” (isolated from *P. africana* and used as a stimulant of the central nervous system. Alkaloids from this genus are used as analgesic and anti-paludism agents (Khuong-Huu et al., 1972; Ratle et al., 1966) (Figure 3).

The main structural tissue constituents of *P. laevigata* pods and duramen are sugars, i.e., saccharose, glucose, fructose and xylose, as well as sulphur amino acids and phenolic compounds (Carrillo-Parra et al., 2008; Díaz-Batalla et al., 2018). In an acetone/water extract, three flavonoids, namely (-)-epicatechin (+)-catechin and taxifolin, were identified by HPLC (Carrillo-Parra et al., 2008) (Figure 4).

Chemical analysis of mesquite flour obtained from the tree pods revealed the presence of six fatty acids: palmitic (C16:0), palmitoleic (C16:1), stearic (C18:0), oleic (C18:1), linoleic (C18:2) and linolenic acid (C18:3). Some of these fatty acids i.e., linoleic, palmitic and stearic acids play an important role in multiple functions in the body; for instance, an influx in the brain function, in cardiovascular system health, digestion, allergies, immunity and vision (Cruz-Gracida et al., 2019).

Figure 2. Compounds identified in different parts of *Prosopis juliflora* and their pharmacological properties.

Figure 3. Chemical structures elucidated from *Prosopis* species.

The antibacterial activity of two bipeptides isolated from *Prosopis* seeds (obtained inside the tree pods) against the pathogenic bacteria *Bacillus cereus* has recently been reported (Acosta-Salas et al., 2020).

Figure 4. Chemical structures of Epicatechin, Catechin and Taxifolin identified in *Prosopis laevigata*.

Figure 5. Chemical structures of compounds isolated from in *P. laevigata*.

In a recent study, the anthelmintic activity of a hydroalcoholic extract obtained from *P. laevigata* leaves was assessed against *Haemonchus contortus*, one of the most pathogenic agents affecting small ruminants all over the world; the extract had 100% *in vitro* ovicidal and larvicidal activity and contained three known flavonoids: isorhamnetin, luteolin and 4'-O-methylcatechin from an ethyl acetate fraction. Isorhamnetin was the compound identified as responsible for the nematocidal activity (Delgado-Núñez et al., 2020) (Figure 5). *Prosopis* spp. offer a wide variety of compounds with enormous medicinal potential, and this interesting Fabaceae plant should be further explored to increase its potential use in public health.

ETHNOPHARMACOLOGICAL USES OF *PROSOPIS* SPECIES

Plants have been used in the control of various diseases for ages, mainly on an empirical basis, contributing to public health particularly in rural zones. This knowledge has been passed down from generation to generation, and nowadays, such “alternative” methods are considered highly valuable. For instance, in India, *P. juliflora* is frequently used to cure rheumatism, as an astringent and as a cure against scorpion stings and snakebites (Wassel et al., 1972). Additionally, *Prosopis* species have been used in India as a diuretic and in the treatment of liver and eye diseases (Chopra et al., 1956). In Pakistan, pregnant women consume powdered *Prosopis* flowers mixed with sugar to prevent spontaneous abortion (Kirtikar and Basu, 1984; Marwat et al., 2011). Additionally, species of *Prosopis* have been

reported to cure some sexually transmitted diseases such as gonorrhoea caused by *Neisseria gonorrhoeae* (Cáceres et al., 1995). Other empirical applications are associated with *P. cineraria*, for example, the use of the plant as an anthelmintic and against leprosy, dysentery and asthma symptoms in the Tharr Desert, India (Garg et al., 2003).

Ethnopharmacological studies have shown that some species of *Prosopis*, such as *P. africana*, *P. alba*, *P. cineraria*, *P. farcta*, *P. glandulosa*, *P. juliflora*, *P. nigra*, *P. ruscifolia* and *P. spicigera*, are commonly used in traditional medicine in several parts of the world to treat various diseases (Table 1). Nevertheless, the species with the highest benefits in public health are *P. juliflora*, *P. africana* and *P. cineraria* (Ahmed et al., 2015; Yaseen, et al., 2015; Suroowan et al., 2017; Umair et al., 2017; Aziz et al., 2018; Younis et al., 2018; Suárez et al., 2019).

POTENTIAL USE OF *PROSOPIS* SPECIES IN DISEASE CONTROL

In the last decades, the medicinal use of plants of the genus *Prosopis* has been widely studied, and nowadays, there is a wide and detailed catalogue of information about the secondary metabolites of pharmacological relevance, particularly against some specific diseases. Plants survive under various biotic and abiotic stress conditions and have developed different barriers of defence; some of these are chemical responses against wounds caused by the attack of pathogenic microorganisms, which trigger the synthesis of compounds called secondary metabolites (Sepúlveda-Jiménez et al., 2003). As previously mentioned, various studies report phytoconstituents such as alkaloids, tannins, phenolic compounds, steroids, terpenes and flavonoids with importance in public health (Ruiz-Nieto et al., 2020). In this context, using natural compounds obtained from plants with medicinal properties, i.e., *Prosopis* species, offers an alternative focus against certain diseases and pathogenic microorganisms of medicinal importance. For example, *in vitro* bactericidal activity of *Prosopis glandulosa* against *Vibrio cholera*, *Salmonella* spp., *Salmonella thypimurium*, *Streptococcus agalactiae* and *Enterococcus faecium* has been recorded by Sánchez et al. (2010) and Valenzuela-Balderas et al. (2017). Reports about the chemical and pharmacological composition of some *Prosopis* species, such as, *P. juliflora*, *P. africana* and *P. cineraria*, include a long list of uses and applications as well as their nutritional benefits and effectiveness as traditional medicine. These species are considered suitable candidates for deeper phytochemical analysis searching for natural medicinal phytochemicals. Some *Prosopis* species share phytochemical and secondary metabolite characteristics that have been associated with several diseases as well as a wide pharmacological response in certain cases. Some *Prosopis* species, as well as their aerial parts, metabolites and pharmacological activities, are listed in Table 2.

Bactericidal and fungicidal activity has been associated with specific alkaloids: juliprosinene and isojuliprosine, as recorded by Ahmad et al. (1989) and Nakano (2010), respectively. Juliflorine also shows activity against Alzheimer's, according to Choudhary et al. (2005), and some flavonoids with antioxidant effects, i.e., α -mesquitol, have been reported (Sirmah et al., 2009). These benefits of phytochemical compounds significantly contribute to reducing the effects of various diseases, including chronic diseases, all over the world (Afrin et al., 2016). *Prosopis* species have been successfully used in traditional

medicine for about 1,000 years to cure many diseases (Giovannetti et al., 2008). In recent decades, scientific studies have explored and corroborated the medicinal properties of this group of plants. The pharmacological potential of secondary metabolites of *Prosopis* species is an important alternative tool of control diseases, and studies on the bioactive molecules from this genus contribute to the development of more natural and practical approaches in public health.

PROSOPIS SPECIES IN THE CONTROL OF DISEASES OF ANIMALS

Since remote times, farmers closely working with animals have been facing numerous health problems in their flocks, forcing them to learn how to restore the health of their animals. This continues practice has allowed them to gain experience in the development of ethnoveterinary tools. Ethnic farmers have established a set of traditional medicinal recipes, which have been handed down through generations (Dassou et al., 2020). When we think of traditional medicine applied to animals, it is important to consider that ethnoveterinary medicine has been existing since remote times, since humans closely living with animals have learned from animals based on their self-treatment behaviour by selecting and feeding on herbs (Miara et al., 2019).

Most medicinal compounds used in the control of human diseases are being used in a similar way in animals. Interestingly, some phytotherapies were initially used in animals and only later in humans and/or vice versa, using the same herbs, compounds and manipulative techniques (McCorkle and Mathis-Mundy, 1992).

As we have mentioned early in this chapter, the genus *Prosopis* is used in a wide of applications, many of them only on an empirical basis by humans, mainly in rural zones in many countries around the world.

The genus *Prosopis*, similar to other members of the Fabaceae family, contains important nutritional components. For example, the various species are an excellent source of crude protein, energy and structural carbohydrates, making them (*per se*) an important natural stimulant of unspecific immunological response associated with the self-defence of cells against several diseases (Ketcha-Wanda et al., 2014). Additionally, plants of the genus *Prosopis* produce several bioactive compounds derived from their secondary metabolism, including condensed tannins, flavonoids, saponins and other phenolic compounds that have been associated with a significant medicinal activity (Ram et al., 2020). These benefits make *Prosopis* plants as viable option as nutraceutical food for cattle and small ruminants (Malik et al., 2013). *Prosopis* spp. leaves (mesquite) have been successfully used in ruminant diets as a nutritional supplement at inclusion levels of 20–40% (Yasin and Animut, 2014; Ruiz-Nieto et al., 2020). Likewise, *Prosopis* species have numerous medicinal properties, including antimicrobial (Yarkwan, 2020), anti-inflammatory (Abodola et al., 2015, Nodushan et al., 2020), antifungal (Miri et al., 2020), skin wound curative (Yadav et al., 2018), antidiabetic (George et al., 2011; Alsaadi et al., 2015), antiprotozoal, cestocidal (Faten and Al-Azziz, 2011) and nematocidal activities (Delgado-Núñez et al., 2020).

Table 1. Traditional use of Prosopis species against various diseases

Species	Part of the plant	Disease/bioactive effect	Mode of use	Location	References
<i>P. juliflora</i>	Bark	Asthma	Oral	Madhya Pradesh, India	Wagh et al., 2018
	Xerophyte shrub	Asthma, cough	Unspecific	Pakistan	Younis et al., 2018
	Leaves, gum	Analgesic, boils, conjunctivitis, toner, muscle pain	Oral	Sindh Desert, Pakistan	Yaseen et al., 2015
	Leaves	Lactation and expectorant	Oral	Pakistan	Aziz et al., 2018
	Leaves, stems, fruits	Eye problems Traumatism Aphrodisiac, intestinal worms	Eye drops Rum macerated balsam	Paraguana Peninsula, Venezuela	Taïma, 2017
	The whole plant, flowers stems, leaves	Galactagogo, kidney stones, toothache, breast cancer asthma, boils	Oral, topic, as a teeth brush	Punjab, Pakistan	Umair et al., 2017
	Branches and leaves	Diabetes	Unspecific	Durango and Coahuila, Mexico	Landeros et al., 2018
<i>P. cineraria</i>	Leaves, bark, flowers, Pods and timber	Menstrual disorders, contraceptive, abortion prevention	Oral	Pakistan	Tariq et al., 2018
	Fruits and pods	Asthma	Unspecific	Pakistan	Younis et al., 2018
	Leaves, bark, stems, flowers fruits	Liver tonic, boils and ampules, pancreatic stones, leucorrhoea, calculus, chronic dysentery, eye cataracts	Oral, topic, eye drops	Punjab, Pakistan	Umair et al., 2017
	Fruits	Body tonic, leucorrhoea	Oral	Thar Dessert (Sindh), Pakistan	Yaseen et al., 2015
	Flowers	Rheumatism	Oral	Pakistan	Suroowan et al., 2017
	Fruits	Asthma, cutaneous eruption	Topic	Southern Kerman, Iran	Sadat-Hosseini et al., 2017
	Leaves and stems	Spasms, diabetes, liver infection, diarrhoea, kidney stone extraction bladder and pancreas fever, flu	Oral	Bahawalnagar, Punjab, Pakistan	Ahmed et al., 2015
<i>P. alba</i>	Leaves Pods Bark	Eye cataracts, dyspepsia, earache, toothache, bone fracture pain relief	Eye drops Oral Ointment	Oman (Arabia)	Ghazanfar and Alsabahi et al., 1993
	Resin	Conjunctivitis, post-abortion pain	Oral	Wichi Village, de Salta Province, Argentina	Suárez, 2019
	Leaves	Malaria	Oral	Nigeria	Wagh et al., 2018
<i>P. africana</i>	Leaves, bark, roots	Pregnancy pains, delivery, lactation, newborn diseases, cutaneous inflammation (wounds and burns)	Unspecific	Guinea-Bissau	Catarino et al., 2016
	Bark from stems	Malaria	Oral, shower	Sub-district of Sélingué, Mali	Diarra et al., 2015
	Roots	Analgesic anti-inflammatory	Oral	Nigeria	Salihi et al., 2018
<i>P. glandulosa</i> Torr	Inflorescences	Stomach ache	Oral	Nuevo Leon, Mexico	Estrada-Castillón et al., 2018
<i>P. ruscifolia</i>	Leaves	Conjunctivitis, stomach-ache, skin pimples, cutaneous eruption, scabies, calluses, fever, birth delivery and post-birth delivery, diarrhoea, pediculosis, otitis	Oral	Wichi Village, de Salta Province, Argentina	Suárez, 2019
	Fruits	Constipation and antipyretic	Oral	Jahrom, Iran	Nasab and Esmailpour, 2018
<i>P. farcta</i>	Roots	Hypoglycaemic and hypotensive	Unspecific	Jordania	Afifi et al., 1993

<i>P. tamarugo</i> <i>P. alba</i>	Leaves and pods	Catechin	Antioxidant	Astudillo et al., 2000
<i>P. cineraria</i>	Whole plant	Alkaloids	Anticonvulsive activity Anti-hyperglycaemia and antioxidant	Sachdeva et al., 2014
<i>P. africana</i>	Leaves, roots and stems Bark of stems	Tannins, flavonoids	Antitrypanosomal	Atawodi et al., 2009
<i>P. chilensis</i>	Leaves	β -Phenethylamine, tryptamine	DNA binding activity	Astudillo et al., 2000

Table 3. Examples of medicinal effects of Prosopis species against different diseases in animals and under different experimental conditions

Prosopis species	Isolated compound	Activity	Animal specie	Author
<i>P. juliflora</i> (pods)	Alkaloid-enriched extracts	Antimicrobial, feed additive for ruminants	<i>In vitro</i> study	dos Santos et al., 2013
<i>P. farcta</i> (fruits)	Ethanollic extract	Antidiabetic	Male rats (Wistar rats)	Dashtban et al., 2016
<i>P. glandulosa</i>	2,3-dihydro-1H-indolizinium alkaloid-prosopilosidine	Antifungal (<i>Cryptococcus neoformans</i>)	Mice (murine model)	Ashfaq et al., 2018
<i>P. juliflora</i> (pods and leaves)	Julifloridine and juliprosopine	Antimalarial	Mice (murine model)	Batista et al., 2018
<i>P. juliflora</i> (leaves)	Methanolic extract	Anticancer	Mice	Utage et al., 2018
<i>P. juliflora</i> (leaves)	Alkaloids	(Antibacterial) Sub-clinical mastitis	Cows	Shah et al., 2018

Based on an extensive revision of the available literature about *Prosopis* spp., most publications have focussed on investigating their medicinal properties. However, other studies have explored its potential use in the control of diseases of animals. It is important to remark that some species of *Prosopis* have beneficial effects in animals, improving or restoring the health of laboratory animals, which is crucial when exploring their use either in animals and/or in diseases of importance in public health. For example, a wound care curative effect was observed using a methanolic extract obtained from *P. africana* stem bark, which reduced the bleeding/clotting and coagulation time in rats (Ezike et al., 2009). Additionally, a hypoglycaemic effect has been reported for 24-methylencycloartan-3-one, a compound obtained from *P. juliflora* pods, in alloxan-induced diabetic rabbits (Alsaadi et al., 2015). An antipyretic effect of a *P. juliflora* ethanolic extract prepared in Brewer's yeast in rats has been reported by Gobinath et al. (2013), whereas an anti-ulcer effect has been observed in ethanol-induced gastric ulcers in rats treated with *P. juliflora* ethanolic extract (Reddy et al., 2014). In another study, an anodyne effect (pain reliever), using a *P. glandulosa* paste prepared with leaves and fruits of the plant and applied to painful bone fractures in animals, has been observed (Khan et al., 2009), and in another study, *P. glandulosa* demonstrated antidiabetic activity in rats with diabetes and in insulin resistance models (George et al., 2011). Other *Prosopis* species, i.e., *P. farcta* (roots), are a promising natural drug for cardiovascular disorders in traditional medicine. In this regard, studies assessing an aqueous extract of *P. farcta* root have been performed using rabbits with high-cholesterol-diet-induced hypercholesterolemia as a study model (Saidi et al., 2016).

A list of medicinal properties of *Prosopis* species against different diseases either under *in vitro* or *in vivo* in different animal species is shown in Table 3.

EXPLORING THE POTENTIAL USE OF *PROSOPIS* SPECIES AS A NATURAL ANTIPARASITIC IN ANIMALS

Under natural conditions, animals show a selective feeding behaviour, especially when they suffer from certain diseases, including parasitosis (Torres-Fajardo et al., 2019). Such behaviour corresponds to a natural self-deworming system (de Roode, 2013). Some groups of compounds with anti-parasitic activity have been identified in different *Prosopis* species,

including tannins, terpenes, coumarins, phenolic compounds, flavonoids and alkaloids (Prabha et al., 2014). It is important to consider that when animals feed on Fabaceae plants such as *Prosopis*, two natural systems against parasites occur in the organism. First, the high nutritional contribution, mainly protein, offered by these plants strengthens the body's defence system, acting as a natural stimulus of the immune system, as mentioned above. Additionally, the molecules identified in the phytochemical profile of *Prosopis* exert an anthelmintic effect that has been identified in many *in vitro* and *in vivo* studies against veterinary parasites (Rahman et al., 2011). Table 4 provides a list of antiparasitic and anthelmintic properties of *Prosopis* species.

Table 4. Examples of the anti-parasitic effect of *Prosopis* species under different conditions

<i>Prosopis</i> species and part of the plant	Extracts/Compounds	Experimental conditions/Biological activity	Blank parasite	Author
<i>P. farcta</i> (leaves)	Alkaloid-enriched extracts	Scolicidal	<i>In vitro</i> study (<i>Echinococcus granulosus</i>)	Hammoshi et al., 2006
<i>P. juliflora</i> (fruits)	Methanolic extract	Antiplasmodial, antileishmanial and antitrypanosomal	<i>In vitro</i> study	Al-Musayeib et al., 2012
<i>P. juliflora</i> (pods)	---	Antiprotozoal	<i>In vitro</i> study (<i>Leishmania infantum</i> , <i>Trypanosoma brucei</i> , <i>T. cruzi</i>)	Al-Musayeib et al., 2012
<i>P. juliflora</i> (leaves)	Aqueous extract	Anthelmintic	<i>In vivo</i> study (sheep)	Mutembei et al., 2015
<i>P. glandulosa</i> (leaves)	Juliprosopine	Anthelmintic	<i>In vitro</i> study (<i>Haemonchus contortus</i>)	Kipyegon et al., 2015
<i>P. cineraria</i> (bark)	Ethanol extract	Anthelmintic	<i>In vitro</i> study (<i>Cotylophoron cotylophorum</i>)	Manigandan and Veerakumari 2015
<i>P. juliflora</i> (pods)	Julispronine	Anthelmintic	<i>In vitro</i> study (<i>H. contortus</i> , <i>Trichostrongylus</i> spp. and <i>Oesophagostomum</i> spp.)	Lima et al., 2017
<i>P. juliflora</i> (pods and leaves)	Julifloridine and juliprosopine	Antimalarial	<i>In vivo</i> study mice (murine model)	Batista et al., 2018
<i>P. laevigata</i> (leaves)	Isorhamnetin	Anthelmintic	<i>In vitro</i> study (<i>Haemonchus contortus</i>)	Delgado-Núñez et al., 2020

Recently, other studies have investigated the anthelmintic activity of different parts of the plant using different isolation strategies, mainly maceration with organic solvents, to separate groups of compounds by polarity grades, followed by chromatography analysis; the results are promising. *Prosopis laevigata* organic extracts have been explored in terms of anthelmintic activity against one of the most pathogenic parasites of small ruminants, *Haemonchus contortus*. For instance, the *in vitro* mortality of *H. contortus* infective larvae by the action of hexanic extract of *P. laevigata* obtained from leaves and stems was assessed, and 51, 81 and 86% larval mortalities were recorded after 24, 48 and 72 h post-exposure to the extract, respectively (López-Aroche et al., 2008). In another study, an *n*-hexanic extract from *P. laevigata* leaves was evaluated as a natural dewormer against *H. contortus* using gerbils as an *in vivo* model, with 100 µL as a unique intra-peritoneal dose. The authors reported a maximum reduction of 53% in the recovery of worms at necropsy, providing evidence of the anthelmintic effect of this extract (de Jesús-Gabino et al., 2010).

In a recent publication by Delgado-Núñez et al. (2020), a chemical bio-guided study was conducted using a hydroalcoholic extract prepared with dried leaves of *P. laevigata* against *H. contortus*. The authors reported a potent *in vitro* anthelmintic effect of this extract against

two exogenous stages of this parasite (eggs and larvae) and found a compound called isorhamnetin, which was responsible for the nematocidal activity. The contents of constitutive chemical compounds in pods of another *Prosopis* species, *P. juliflora*, have been reported by Lima et al. (2017), who described the presence of an alkaloid compound called juliprosopine. This molecule was associated with ovicidal and larvicidal activity against three gastrointestinal parasitic nematodes of sheep and goats: *H. contortus*, *Trichostrongylus* spp. and *Oesophagostomum* spp. (Lima et al., 2017). Encapsulated ethanolic extracts of *P. juliflora* roots have shown 50% ovicidal activity against *H. contortus*, with only 0.35 and 0.74 mg/mL (Kipyegon et al., 2015). As shown in this present chapter, *Prosopis* species are important due to their use in traditional medicine, and they could be used as a potential tool in the control of many diseases of livestock and other domestic species

CONCLUSION

The wide range of beneficial properties of the Fabaceae *Prosopis* has been used since remote times. The plants play an important role as forage for cattle and small ruminants, as a source of fuel, firewood and charcoal as well as timber trees. The genus is also used in bioethanol production, reforestation and bioremediation. In addition, *Prosopis* species contain several compounds and molecules derived from their secondary metabolism with potential use in public health and veterinary medicine. The medicinal properties of this genus confirm that traditional medicine has correctly used these plants on an empirical basis. Beyond these properties, new biological activities have recently been found and applied in public and veterinary health, offering new alternative tools of control for many diseases from a natural and sustainable perspective.

Chapter 551

SCHIZOPHRENIA: AN OVERVIEW FROM PUBLIC MENTAL HEALTH PERSPECTIVE

Pragya Lodha^{1,*} and Apurvakumar Pandya², PhD

¹Clinical Psychologist, Mumbai, India

²Indian Institute of Public Health Gandhinagar, India

ABSTRACT

Schizophrenia is a chronic and severely disabling mental illness representing a serious public mental health problem across the globe. It is an illness that has multifarious symptom manifestations across patients, and the cumulative effect is always severe and long-lasting. Schizophrenia unarguably remains one of the most debilitating mental illnesses with multifactorial causes. It creates a burden not only for the patient but also for the family, community, and nation. The chapter discusses etiology, epidemiology, comorbidities, diagnosis, and prognosis. It presents a synthesis of current evidence on treatment modalities - moving from a biomedical approach to a more integrative approach. Schizophrenia is a common psychiatric condition that most clinicians encounter in their routine practice. Early screening and timely treatment is linked with reduced chronicity and severity. However, screening of schizophrenia at community level is not prioritized. The chapter concludes by arguing that community level screening, timely diagnosis and integrating traditional medicine and traditional healing practices rooted in a given cultural and religious context as treatment plans are potential public health strategies. More research is needed to generate evidence on the above areas.

Keywords: schizophrenia, mental illness, psychosis, positive symptoms, negative symptoms, public mental health

INTRODUCTION

Schizophrenia is a chronic and severe mental illness affecting the most basic human processes of perception, emotion, and judgment. Approximately 20 million people live with schizophrenia globally, which will continue to rise (James et al., 2018). Schizophrenia is associated with considerable disability impacting educational, social, occupational, and economic productivity (Chong et al., 2016; WHO, 2019). People with schizophrenia are more likely to die early than the general population due to comorbidities such as cardiovascular, metabolic, and infectious diseases (Laursen et al., 2014).

Although schizophrenia is treatable, more than 69 percent of people with schizophrenia are not receiving appropriate mental health care (WHO, 2019). Approximately 90% percent of people with untreated schizophrenia are from low- and middle-income countries (WHO, 2019). Restricted access to mental health services is a critical challenge. Research indicated that people with schizophrenia are less likely to seek care than the general population (Lora et al., 2012). Further, stigma, discrimination, and violation of human rights of people with schizophrenia also act as barriers in access to timely appropriate mental health care (Kanak et al., 2017; Poreddi et al., 2013; Singh et al., 2016). Prevalence of schizophrenia, challenges in accessing appropriate and timely mental health care, and stigma make schizophrenia a serious public mental health problem.

This chapter discusses epidemiology, comorbidities, causal factors, diagnosis, prognosis, and treatment modalities by synthesizing current evidence. The chapter gives an overview of different treatment modalities, from a biomedical approach to a more integrative approach that evolved in the last two decades. Authors argue that integrating traditional medicine and traditional healing practices rooted in a given cultural and religious context is imperative in the public health system. Lastly, authors present implications for future research and public health practices.

BRIEF HISTORY AND EVOLUTION OF NOMENCLATURE

The emergence of schizophrenia as a medical condition was noted worth studying only after the eighteenth century. Till then, the general perspective around various psychotic disorders was that of insanity or madness (Sadock & Sadock, 2009). It was Belgian psychiatrist, Benedict Morel (1852), in the late nineteenth century who formally spoke about schizophrenia, addressing it as ‘*démence précoce*.’ Later, the German psychiatrist Emil Kraepelin (1896) introduced the term ‘*dementia praecox*’ to a group of illnesses beginning in adolescence that ended in dementia as the individual progressed into adulthood. Later, Kraepelin further formalised the construct by integrating the contemporary descriptions of catatonia by Kahlbaum (1863), that of ‘*hebephrenia*’ by Hecker (1871), and his own “*dementia paranoia/praecox*” into a single disorder with an early onset, poor prognosis, and 36 psychic or psychological symptoms and 19 bodily or physical symptoms. Kraepelin's description explained the presence of negative symptoms (described as emotional dullness, failure of mental activities, loss of mastery over volition, of endeavor, and the ability for independent action), as well as positive symptoms (described as a loss of the inner unity of the activities of the intellect, emotion, and volition in themselves) (Lavertsky, 2008).

Table 1. Emile Kraepelin's 'clinical forms' (Kraepelin, 1919; Kraepelin, 1990)

- | |
|--|
| <ul style="list-style-type: none"> • Dementia praecox simplex: impoverishment and devastation of the whole psychic life, which is accomplished quite imperceptibly. • Hebephrenia: insidious change of personality with shallow capricious affect, senseless and incoherent behaviour, poverty of thought, occasional hallucinations, and fragmentary delusions, progressing to profound dementia. • Depressive dementia praecox (simple and delusional form): the initial state of depression followed by slowly progressive cognitive decline and avolition, with or without hypochondriacal or persecutory delusions • Circular dementia praecox: prodromal depression followed by the gradual onset of auditory hallucinations, delusions, marked fluctuations of mood, and aimless impulsivity. • Agitated dementia praecox: acute onset, perplexity or exaltation, multimodal hallucinations, fantastic delusions. • Periodic dementia praecox: recurrent acute, brief episodes of confused excitement with remissions. • Catatonia: the conjunction of peculiar excitement with catatonic stupor dominates the clinical picture" in this form, but catatonic phenomena frequently occur in otherwise wholly different presentations of dementia praecox. • Paranoid dementia (mild and severe form): the essential symptoms are delusions and hallucinations. The severe form results in a "peculiar disintegration of psychic life," especially emotional and volitional disorders. The mild form is a very slowly evolving "paranoid or hallucinatory weak-mindedness" which "makes it possible for the patient for a long time still to live as an apparently healthy individual. • Schizophasia (confusional speech dementia praecox): cases are meeting the general description of dementia praecox but resulting in an end-state of "an unusually striking disorder of expression in speech, with relatively little impairment of the remaining psychic activities." |
|--|

In 1911, a Swiss psychiatrist, Paul Eugene Bleuler, disagreed with the presentation of dementia in dementia praecox and coined the term 'schizophrenia.' The term schizophrenia has its roots in the early 20th century Latin words, *skhizein* meaning 'to split' and *phren* meaning 'mind.' Thus schizophrenia is understood with a characteristic as the splitting of the mind. Bleuler introduced the symptoms of schizophrenia as primary and secondary symptoms. He called the four primary symptoms as the four As, which included abnormal associations, autistic behaviour and thinking abnormal affect and ambivalence. Bleuler's view of the illness being a dissociative process is fundamental to the conceptualisation of schizophrenia and its symptom manifestations. Schizophrenia is a single disease entity in which there is an extensive similarity in the etiology (cause) and pathophysiology (a mechanism) across all patients with the disorder.

Alternatively, schizophrenia is characterized as a clinical syndrome rather than a single disease entity, often understood as having heterogeneity in presentation. This view holds that although patients with schizophrenia share commonalities of signs and symptoms that are enough to differentiate them from other disorders, more than one disease entity is likely to be found within this syndrome (Sadock & Sadock, 2008). There is extensive variability in clinical presentation, disease course, and how patients respond to pharmacological and psychosocial treatment.

The modern-day understanding of schizophrenia is a neuropsychiatric condition (Gur, 2011), classifying as a debilitating psychiatric illness adversely influencing the development of mental capacities in thought, emotion and behavior. In the illness's active phase, the individual experiences delusions, hallucinations, disorganized speech, trouble with thinking, and lack of motivation (APA, 2020). According to the latest Diagnostic and Statistical Manual of Mental Disorders (DSM) Edition 5, schizophrenia is no more classified as various types (schizophrenia was classified under five subtypes of paranoid, catatonic, residual, undifferentiated, and disorganized-till DSM IV-TR) but diagnosed as a schizophrenia spectrum disorder (DSM 5, 2016).

EPIDEMIOLOGY

Schizophrenia is a public health challenge with no society or culture in the world found free from this impairing mental health condition. It affects about 0.5-1 percent of the world's population (approximately 0.85 percent) (Sadock & Sadock, 2008). It is a mythical conception that schizophrenia has a universal prevalence. Difficult to study the exact demographic differences across time; it is found that the incidence is between 8%-43% (McGrath et al., 2008); however, the lifetime prevalence remains more or less the same throughout the world. The recent (2016) global age-standardized point prevalence of schizophrenia was estimated to be 0.28%. However, the point prevalence of schizophrenia, the proportion of the population at a point in time with the disorder, is about 7/1000 in the global population (McGrath et al., 2008).

Age of Onset

Although schizophrenia can occur at any age, the average age of onset tends to be in the late teens to the early 20s for men and the late 20s to early 30s for women. It is uncommon for schizophrenia to be diagnosed in a younger than 12 years or older than 40 years (National Alliance of Mental Illness, 2020). Schizophrenia in children younger than 12 years, early onset, is referred to as Childhood onset Schizophrenia or COS and is very rare. In children, COS can often be misunderstood for various other diagnoses. The epidemiologic incidence of the diagnosis based on standardized clinical assessments are lacking. It is generally accepted that the incidence of COS is less than 0.04% based on the observations from the National Institutes of Mental Health (NIMH) cohort (Driver et al., 2013).

Ever since the DSM III-R, the late onset of schizophrenia has been anchored at 44 years of age, accounting for 15-20% of all the cases (APA, 1987). The same continues to be accepted for ICD-11 (Gaebel, 2012). Most patients with late onset usually have had an onset in the middle age but may remain mild, remain unidentified or go undiagnosed. Psychosis after the age of 65 years signifies very-late onset schizophrenia; it is most often secondary to medical conditions like dementia or neurodegenerative disorders (Sable et al., 2002).

Gender

The existence of gender differences in the incidence of schizophrenia has been subject to debate. The traditional consideration that the prevalence of schizophrenia is similar among men and women is a myth (Wyatt et al., 1988) and has been challenged to evidence gender differences. Several studies indicate that the incidence rate of schizophrenia is higher in men. The mean age of onset for men is usually 18–25 years, while the mean age of onset in women is 25–35 (Ochoa et al., 2012). A systematic review analysis of 31 studies reveals that the male to female rate ratio can be estimated to be 1.4:1 (McGrath & John, 2005). Though no gender differences have been found in the prevalence of schizophrenia in epidemiological studies, it seems that more new cases of schizophrenia have been detected in men (Ochoa et al., 2012).

Urbanicity and Socio-Economic Status

The incidence of schizophrenia in rural and urban areas are somewhat similar. However, expressly, a greater prevalence of schizophrenia is noted among the urban population and those belonging to the lower socio-economic classes. This difference is generally attributed to the "social drift" phenomenon in which vulnerable individuals tend to lose their occupation which pushes them into pockets of poverty (Sadock & Sadock, 2008). A strong link between socio-economic status and schizophrenia has been highlighted by encompassing income inequality, low parental socio-economic status, migration, and overall socio-economic deprivation (Lee et al., 2018). Studies have also shown correlations between poverty and the incidence of schizophrenia. However, a challenge that remains to pose is the inconsistent methodologies and differing urbanization rates.

Race and Ethnicity

Understanding the prevalence of schizophrenia in the context of race and ethnicity is a challenging task, given that the current diagnostic criteria do not display satisfactory cultural competence. Some studies speak of differences in incidence and symptom presentation of schizophrenia spectrum disorder across racial and ethnic groups. However, more important is to address the nuance if these differences arise more for clinician biases, lack of cultural competence of diagnostic criteria and. Further research is required to clarify the racial/ethnic conundrum in the context of schizophrenia spectrum disorder (Gurak et al., 2018).

ETIOLOGY

The etiological processes of schizophrenia continue to be unknown. It is debatable yet to see if schizophrenia is a neurodevelopmental (impacting brain development) or a neurodegenerative (affecting the normal and healthy developed brain) disorder. Although Kraepelin believed that schizophrenia had an early onset and was a chronic deteriorating disorder, examining the clinical course of the illness has not helped clarify this issue. Clinical

features like subtle neurological manifestations, cognitive dysfunction, and disturbances in affect are some primary symptoms seen in patients with schizophrenia- it remains uncovered whether these arise from an injured brain with lesions or are a function of neurodevelopmental abnormalities of the developing brain. However, a good deal of understanding of the risk factors of schizophrenia becomes a reliable guide to understanding probable causative factors. The heterogeneity of the illness further exacerbates the complexity of etiopathophysiology. Despite this, there are the following plausible etiological considerations to understand the causation of schizophrenia spectrum disorder:

Diathesis Stress Model

One of the fundamental ways of explaining the development of schizophrenia is through the diathesis stress model. It proposes that the individual who develops schizophrenia has a predisposition of biologic vulnerability or 'diathesis' triggered by stress and leads to schizophrenia symptoms. Stress can be biological, psychological, genetic, or environmental.

Genetics

There are single-gene and polygenic theories proposed to understand the development of schizophrenia. Though none of the theories are conclusive, polygenic theories are given more weightage as plausible causative factors.

The risk for schizophrenia is higher in consanguineous families than in the general population. Among twin studies, it is yet higher in monozygotic twins versus dizygotic, with a concordance rate for schizophrenia between 40 to 50 percent with heritability estimates about 80-85%. This concordance rate is 4-5 times that in dizygotic twins or the rate of occurrence found in other first-degree relatives such as siblings, parents, or offspring. Surprisingly, genetic factors have also been found in second- and third-degree relatives in whom generally the genetic load is expected to be lowered (Kavanagh et al., 2015). Adoption studies have also delineated the greater prevalence in biological parents of adoptees with schizophrenia versus adoptive parents. Studies have also found higher rates of schizophrenia when born to unaffected parents but reared by parents with schizophrenia (Leo, 2006).

There has been documentation of robust findings on family, twin and adoptive studies in regards to contribution of genetic factors to the etiology of schizophrenia. Evidence for genetic factors have been established in almost all cases of schizophrenia. However, it is not yet known which specific genes are underlying, nor the contribution of specific proteins is known to the pathophysiology of schizophrenia. Recent linkage analyses have revealed the potential location on chromosome 6 and contributions associated with chromosomes 4, 8, 15. Research studies also talk about microdeletion of a region on chromosome 22, called 22q11, that has been found in cases of schizophrenia and thus a supposed causal factor (Escudero et al., 2014).

Novel technologies such as next-generation sequencing (NGS), genome-wide association studies (GWAS), and the Clustered Regularly Interspaced Short Palindromic Repeats-associated nuclease 9 (CRISPR/Cas9) genome editing platform are capable of interrogating

and editing the genome directly. These efforts have led to identifying essential loci and genes susceptible to schizophrenia (Zhuo et al., 2019).

Findings to date are not conclusive and demand accelerated research to clarify the disorder's heritability and genetic load. Alternatively, Torrey and Yolken (2019) have argued that schizophrenia may be a pseudo-genetic condition with an overestimation of heritability linkages which could be better explained by infectious transfer (Torrey & Yolken, 2019). There is a need for further gene-environmental studies to clarify this stand. In addition, epigenetic findings have surged in research, with time, compared with healthy controls. Many of the findings revealed associations with epigenetic modulations of genes regulating neurotransmission, neurodevelopment, and immune function, as well as differential miRNA expression (Smigielski et al., 2020).

Neurotransmitter Theories

1. Dopamine hypothesis: Dopamine alterations are related to schizophrenia (Wang et al., 2012). An increase of dopaminergic activity in the mesolimbic region and decreased activity in the prefrontal region is implicated in positive and negative symptoms of schizophrenia, respectively (Brisch et al., 2014). Recent research has outlined the dopaminergic activities, and the interaction with other neurochemicals is essential to explain the etiology for schizophrenia. Dopamine receptors D1 through D5 have been identified to play a role in the etiology of the illness. Another oft researched hypothesis is Gamma-aminobutyric acid (GABA), which discusses that patients with schizophrenia have fewer GABAergic neurons in the hippocampal area. Decreased GABA activity has also been found to increase dopamine activity implicated in schizophrenia.
2. Norepinephrine hypothesis. It is another suggestion while understanding the development of schizophrenia that posits a relationship between increased norepinephrine levels and consequent sensitization of sensory inputs. Norepinephrine is also implicated in the impaired capacity of emotional regulation and decreased ability to feel pleasure- anhedonia- symptomatology of schizophrenia.
3. Serotonin hypothesis. Hyperserotoninemia and hyposerotoninemia forms of abnormal serotonin metabolism are reported in patients with schizophrenia. Specifically, antagonism at the serotonin 5-HT₂ receptor has been emphasized. Chronic widespread stress-induced serotonergic overdrive in the anterior cingulate cortex (ACC) and dorsolateral frontal lobe of cerebral cortex in schizophrenia is the primary cause of the disease (Eggers, 2013).
4. Glutamate hypothesis. Hypofunction of the glutamate N-methyl-D-aspartate (NMDA)-type receptor is theorized to cause both positive and negative symptoms of schizophrenia. This hypothesis furthers the explanation with glutamate, including hyperactivity, hypoactivity, and glutamate-induced neurotoxicity that are underpinned in the development of schizophrenia.

Neurodevelopmental Theories

Weinberger, Murray & Lewis formulated the neurodevelopmental hypothesis of schizophrenia. This understanding propounds the development of schizophrenia later in life due to abnormal neuronal functioning and neural development in childhood. Structural brain abnormalities, frequent occurrence of cognitive and motor abnormalities at a young age, and the possible presence of neonatal lesions (Owen et al., 2011) have been some ways of tracing back to understand the development of schizophrenia. There is evidence for abnormal neuronal migration during the second trimester of fetal development (Hwang et al., 2019).

Neuro Immunovirology

The immune and viral hypotheses of schizophrenia have existed for far longer, though with weak empirical efficacy. These theories have been difficult to conduct and study because any potential marker of an immune or viral process associated with schizophrenia is limited in application to few cases. Besides, it is also subject to interpretation where the immunoviral hypothesis could be better explained by conditions associated with the disease (e.g., high rates of exposure in crowded hospitals with chronically ill patients, low socio-economic circumstances, and poor health habits).

Miscellaneous Factors

Some miscellaneous factors that have been hypothesized in the causal explanations for the neurodevelopmental pathological process of schizophrenia include gestational complications and complications during birth, exposure to influenza, Rhesus (Rh) incompatibility, starvation, and births during winter months (Sadock & Sadock, 2008). However, the exact pathophysiological mechanisms associated with these risk factors remain unknown.

PSYCHOSOCIAL THEORIES OF SCHIZOPHRENIA

Various theories embedded in the psychosocial framework have been delineated to understand the roots of the development of the illness (Sadock & Sadock, 2008). Most prominent theories are discussed below.

Psychoanalytic Theories

The classical psychoanalytic foundation laid by Sigmund Freud postulated that early life developmental fixations produce defects in ego development which contribute to the symptoms of schizophrenia. Ego disintegration in schizophrenia represents a return to when the ego was not yet developed or had just begun to be established, explaining the regressive

behavior in schizophrenia. The ego functions are impaired due to how the ego alters the interpretation of reality and the control of inner drives (sex and aggressive instincts). The intrapsychic conflict between fixations from early life and defects in ego fuel psychotic symptoms such as losing touch with reality. As Margaret Mahler explains the child's insecure attachment style, the infant and the mother's reciprocal relationship is distorted. The child fails to grow independent of the mother in the oral phase of development.

Harry Stack Sullivan viewed schizophrenia as a disturbance in interpersonal relatedness. He proposed that schizophrenia is an adaptive method used by patients to avoid panic, terror, and disintegration of the sense of self resulting from cumulative experiential traumas during development.

The psychoanalytic theory also postulates varied symbolism in various symptoms of schizophrenia for individual patients.

Learning Theories

Learning theorists propose that schizophrenia develops in later life in children who learned irrational ways of thinking and behaving to imitate parents with emotional troubles. The presence of poor models in childhood is responsible for the poor interpersonal relationships, which further become a risk factor for the development of schizophrenia.

Double Bind

Gregory Bateson and Donald Jackson coined the double-bind concept to describe a hypothetical family in which children receive opposing and conflicting messages from parents. The messages are centered around behavior, attitudes, and feelings that confuse the child model to follow/learn from. Bateson hypothesizes that children withdraw into a psychotic state to escape the confusion of the double bind, which they find unsolvable. However, the lack of empirical backing does not make the theory fit enough to explain a causal explanation of schizophrenia.

Skewed Families and Family Schism

Theodore Lidz conceptualized two abnormal family behavioral patterns implicated in the development of schizophrenia. There is a prominent divide (schism) between the parents; one parent is overly close to a child of the opposite gender. In the family skew, a skewed relationship between a child and one parent involves a power struggle between the parents and one parent's resulting dominance. Both the family-type dynamics induce stressed adaptation for the person with schizophrenia.

Pseudomutual and Pseudohostile Families

Lyman Wynne described some families suppress emotional expression by consistently using pseudomutual or pseudohostile verbal communication. There is a pretense of cordial communication when there is conflict (pseudomutual), and sometimes families fake conflicts to hide cordiality (pseudo-hostile). In such families, exceptional verbal communication develops, influencing the child's communication patterns. The child fails to integrate messages and is left confused and incomprehensible to the outsiders.

Expressed Emotion

A higher end of emotional expression, especially demonstrated through parental control, over criticism, hostility, and demandingness can trigger the psychotic outbreak in persons with schizophrenia. Many studies have indicated that in families with high levels of expressed emotion, the relapse rate for schizophrenia is high. The assessment of expressed emotion involves analyzing both what is said and how it is said.

PATHOPHYSIOLOGY

The earliest and only way of understanding the neuroanatomy of schizophrenia was the examination of the brain tissue through postmortem. The complexity in discerning the exact neural pathways and pathophysiology of schizophrenia earned it to be "the graveyard of neuropathology," which often caused difficulty understanding if neuropathological findings were a cause or consequence. This is attributed to the heterogeneity of the illness. It is relatively well established that schizophrenia can result from single or multiple disorders of the brain regions. With the understanding of schizophrenia moving away from the gene-based developmental factors, recent research focuses on exploring different neurodevelopmental or environmental causes for the pathophysiology of the illness. Despite the lack of conclusivity, several theories around nature, timing, and the course of the brain change that effort to explain the development of schizophrenia (Lakhan & Vieira, 2009). There has been strong evidence on explaining the linkages between multiple neurotransmitter pathways such as dopaminergic, glutamatergic, GABAergic, and cholinergic neurotransmitter systems with the pathophysiology of schizophrenia (Benes, 2009).

The introduction of neuroleptic drugs for the treatment of schizophrenia and the interest in noninvasive techniques led to further investigation into pathophysiology.

Neuroimaging

Earlier in the years, primary neuroimaging techniques like pneumoencephalography (PEG) and CT scans have provided substantial evidence for enlarged brain ventricles and sulcal widenings, suggesting lesser brain tissue in patients with schizophrenia as compared to controls. Electroencephalography or EEG provided information on cortical surface electrical

activity. Conclusively, PEG, CT nor EEG techniques fell short of providing functional information about the brain.

Decreased cortical gray matter in the temporal cortex, decreased volume of limbic system structures, and increased volumes of basal ganglia nuclei have been found in studies employing magnetic resonance imaging (MRI). Functional imaging studies provide real time functional data, like, recording abnormal patterns of glucose metabolism/blood flow while cognitive tasks were being performed.

Neural Circuits

The biochemistry of the brain plays a fundamental role in the disruptions of brain function involved in schizophrenia, given that information is processed through neurons and neuronal networks (Benes, 2009). An integrative approach of the neuroanatomical understanding with biochemical disruptions is considerable to trace the pathophysiology of schizophrenia. Over the last 30 years, schizophrenia has grown from being conceptualized as a disorder that involves discrete brain areas to a view that schizophrenia is a disorder of neural circuitry in the brain. This paradigm shift in understanding the pathophysiology schizophrenia posits the plausible presence of a structural or functional lesion in the neural circuit that causes various dysfunctions as seen in the illness.

Studies done on the pathophysiology of schizophrenia using postmortem and structural/functional studies have implicated the limbic cortex, especially in the hippocampus (HC) and the anterior cingulate cortex (ACC), with the involvement of abnormal regional cerebral blood flow (rCBF). Each neurocircuitry is responsible for a different set of functions. Dysfunction of one neurocircuitry is independent of that of another. Some symptoms of schizophrenia, such as task difficulty and cognitive symptoms, are mediated as a possible dysfunction of the neuronal activity in the ACC and HC. It has been hypothesized that dysfunction of the anterior cingulate basal ganglia-thalamocortical circuit underlies the production of psychotic symptoms, and dysfunction of the dorsolateral prefrontal circuit underlies the production of primary enduring negative or deficit symptoms (Lakhan & Vieira, 2009).

The production of hallucinations, delusions, and positive formal thought disorder are a function of Wernicke's and Broca's areas and associated cortical and subcortical structures. Although the pathophysiology of schizophrenia remains unknown, clues about its mechanisms are emerging and evolving. (Tamminga et al., 2002).

CLINICAL FEATURES

The clinical features, signs, and symptoms of schizophrenia are not pathognomonic but are commonly found overlapping with those of other psychiatric disorders. Thus, signs and symptoms are not diagnostic in nature without the context of case history and MSE. It is also crucial to incorporate the educational level, intellectual capability, and socio-cultural framework to formulate the diagnosis. Additionally, it is vital to understand and note symptoms' temporal nature while case history taking and examination.

As part of understanding the clinical features of schizophrenia, it is relevant to understand the prodrome phase of schizophrenia. With multiple understandings, prodrome, as described by Keith and Matthews (1991), refers to a 'heterogeneous group of behaviors temporally related to the onset of psychosis' (George et al., 2017). The DSM III (1987) included nine characteristics of the prodrome, as listed below:

1. Marked social isolation or withdrawal
2. Marked impairment in role functioning
3. Markedly peculiar behavior
4. Marked impairment in personal hygiene and grooming
5. Blunted or inappropriate affect
6. Digressive, vague, overelaborate or circumstantial speech, or poverty of speech, or poverty of content of speech
7. Odd beliefs or magical thinking
8. Unusual perceptual experiences
9. Marked lack of initiative, interests, or energy.

However, this has been dropped from DSM IV and ICD-10 onwards and remains characteristic of its illness. Though met with a diagnostic dilemma, it is said that about 75% of patients experience this phase before developing the full-blown illness. A subclinical threshold of symptoms and non-specific anxiety and affective disturbance are seen at least one year before the full blow episode of psychosis. Current estimates say that 1 in 4 of the high-risk patients will progress to schizophrenia (George et al., 2017).

Some experienced clinicians express a *precox feeling*, that is, their inability to establish an emotional rapport with the patients. Anecdotally, it is frequently reported but lacks empirical backing to confirm it as a marker for diagnosing schizophrenia.

Symptoms of schizophrenia are most conveniently understood by desiccating them into positive and negative symptoms. Positive symptoms are abnormally present complaints that cause distress to patients, leading to the experience of not being in touch with reality. Positive symptoms usually classify to be perceptual differences. The most vivid positive symptoms are hallucinations and delusion.

Hallucinations, experienced by nearly 70-75% of patients, are perceptual disturbances affecting any individual's five senses. Auditory hallucinations are the commonest reported hallucination, followed by visual hallucinations, followed by tactile and olfactory. The least reported hallucination is that of taste or gustatory hallucinations. Delusions are more common than hallucinations, observed in more than 90% of patients. A delusion is a false belief that indicates an abnormality in the content of thought. The false belief is not accounted for by the person's cultural or religious background or intelligence level. Based on content (Kiran & Chaudhury, 2009), delusions are categorized as a delusion of persecution (the most frequently encountered delusion), grandiose delusions (also called expansive delusion, all forms of hallucinations can occur), a delusion of infertility (referred to as sexual jealousy by Emile Kraepelin), a delusion of love (erotomania, commoner in women), religious delusion (formed a higher proportion in the nineteenth century than in the twentieth century and are still prevalent in developing countries), nihilistic delusion (reverse of grandiose delusion) and delusion of guilt and unworthiness (may lead to suicide).

Disorganized symptoms include confused and disordered thinking and speech, trouble with logical thinking, and sometimes bizarre behavior or abnormal movements. Disorganized symptoms encompass disorganized thought, speech, and behavior which are incoherent, unrelated, illogical, and sometimes even bizarre.

Negative symptoms signify a lost function or absence of function. Theoretically, there can be a large number of potential negative symptoms. Given the variety of cognitive, emotional, and socio-occupational deficits seen in schizophrenia, excepting defects in the domain of emotion, the rest are not defined as negative symptoms (Sadock & Sadock, 2008), some of the primary ones being:

- Affective flattening/blunting
- Unchanged facial expressions
- Decreased spontaneous movements
- Paucity of expressive gesture
- Poor eye contact
- Affective non-responsivity
- Inappropriate affect
- Lack of vocal inflections

There are additional symptoms to the negative symptoms recognized as associated symptoms called *alogia* (poverty of speech, content of speech, blocking, increased latency of response), *avolition-apathy* (grooming and hygiene, absence at work/school, lack of energy), *anhedonia-asocial* (lack of motivation, lack of interest in interpersonal relationships) and *attention* (social inattentiveness, disorientation). Signs and symptoms must present for at-least six months to make a diagnosis.

COMORBIDITIES

Physical and psychiatric comorbidities are common among patients with schizophrenia. The most predominant comorbid condition seen with schizophrenia is substance abuse, seen in about 47% at lifetime prevalence. A comorbid diagnosis of anxiety and depressive symptoms is also widespread throughout the course of illness. Research (Buckey et al., 2009) shows an estimated prevalence of 15% for panic disorder, 29% for posttraumatic stress disorder, 23% for obsessive-compulsive disorder, and comorbid depression occurs in 50% of patients.

Obesity and metabolic syndrome are among the significant medical comorbidities in schizophrenia, with evidence of a relationship between weight gain or metabolic syndrome and antipsychotic medications (Norlelawati et al., 2012). People with schizophrenia are also at higher risk for hepatitis, cardiovascular diseases, diabetes, sexual dysfunction, and obstetric complications (Santos et al., 2017).

Diagnosis

Schizophrenia is a disorder whose diagnosis is based on the patient's observation and description. Abnormalities are often present on most components of the mental status examination. There are no pathognomonic signs or symptoms. According to the Diagnostic Statistical Manual of Mental Disorders -fifth edition (DSM-5), at-least two of the following five symptoms must present for at least one month. (1) Hallucinations; (2) delusions; (3) disorganized speech; (4) disorganized behavior; or (5) negative symptoms (e.g., flat affect, abulia).

The diagnosis of schizophrenia is often misunderstood leading to erroneous conclusions. Throughout most of the twentieth century, there has been substantial agreement among diagnosticians throughout the world, using seemingly divergent diagnostic approaches, in recognition of typical cases of schizophrenia. There has also been no difficulty in distinguishing schizophrenia from normality.

The identification of several diagnostic issues identified in a body of research in the 1960s and 1970s warranted for developing an adequate diagnostic system which was implemented in DSM-III. This was retained till DSM IV TR and ICD 10. The advent of DSM 5 saw some changes in the way schizophrenia was diagnosed.

The following is the exhaustive criteria of diagnosis according to DSM 5 (DSM 5, 2013).

Table 2. DSM 5 diagnostic classification of schizophrenia

A.	Overall functioning. Level of functioning declines or fails to achieve the expected level.
B.	Thought content. Abnormal (e.g., delusions, ideas of reference, poverty of content). Delusion and hallucinations are not necessary to diagnose if other signs and symptoms are present.
C.	Form of thought. It is illogical (e.g., derailment, loosening of associations, incoherence, circumstantially, tangentiality, over-inclusiveness, neologisms, blocking, echolalia—all incorporated as a thought disorder).
D.	Perception. Distorted (e.g., hallucinations: visual, olfactory, tactile, and, most frequently, auditory).
E.	Affect. Abnormal (e.g., flat, blunted, silly, labile, inappropriate).
F.	Sense of self. Impaired (e.g., loss of ego boundaries, gender confusion, inability to distinguish internal from external reality).
G.	Volition. Altered (e.g., inadequate drive or motivation and marked ambivalence).
H.	Interpersonal functioning. Impaired (e.g., social withdrawal and emotional detachment, aggressiveness, sexual inappropriateness).
I.	Psychomotor behavior. Abnormal or changed (e.g., agitation vs. withdrawal, grimacing, posturing, rituals, catatonia).
J.	Cognition. Impaired (e.g., concreteness, inattention, impaired information processing).

DSM-5 no longer classifies schizophrenia based on subtypes.

Differential Diagnoses

Disorders considered as the differential diagnosis for schizophrenia are primarily divided into medical- neurologic conditions, medical conditions, and psychiatric conditions. However, to further detail, the categorization can also spread across- anatomic lesions, metabolic syndromes, endocrine disorders, infectious illnesses, and vitamin deficiencies.

Some studies have confirmed that schizophrenia can be over-diagnosed, with up to 50% of patients being misdiagnosed as schizophrenia (John Hopkins Medicine, 2019). The following are some essential diagnoses to ensure the sanctity of diagnosis.

Medical-Neurologic Conditions

- Substance-induced—amphetamine, hallucinogens, belladonna alkaloids, alcohol hallucinosis, barbiturate withdrawal, cocaine, phencyclidine
- Epilepsy—especially temporal lobe epilepsy

Neoplasm, cerebrovascular disease, or trauma—especially frontal or limbic

- Other Medical Conditions Acute intermittent porphyria
- AIDS
- Vitamin B12 deficiency
- Carbon monoxide poisoning
- Cerebral lipoidosis
- Creutzfeldt–Jakob disease
- Fabry's disease
- Fahr's disease
- Hallervorden–Spatz disease
- Heavy metal poisoning
- Herpes encephalitis
- Homocystinuria
- Huntington's disease
- Metachromatic leukodystrophy
- Neurosyphilis
- Normal pressure hydrocephalus
- Pellagra
- Systemic lupus erythematosus
- Wernicke–Korsakoff syndrome

Wilson's Disease

- Psychiatric Conditions Atypical psychosis
- Autistic disorder
- Brief psychotic disorder
- Delusional disorder
- Factitious disorder with predominant psychological presentation
- Malingering
- Mood disorders- major depressive disorder & bipolar disorder
- Obsessive-compulsive disorder
- Cluster A and B personality disorders
- Schizoaffective disorder

Schizophreniform Disorder

Diagnostic concepts play a critical role in identifying risk factors, etiology, assess comorbidities, and end-goal of management and treatment of schizophrenia patients. This is met with an inherent challenge of the heterogeneity of the illness and the weakness of the diagnostic concept of the illness as a result of the unknown pathophysiology, etiology, and the wavering presentation of symptomatology. However, the utility of diagnosis is maintained with the spectrum-based understanding of the illness that allows addressing overt symptoms and patient-reported concerns. (Jablensky, 2006).

Diagnostic Tools for Schizophrenia

The first step in diagnosing the illness involves ruling out other mental health disorders and determining that symptoms are not a function of a comorbid condition. Determining a diagnosis of schizophrenia may include:

- i. Case history and MSE: to get a detailed understanding of the presentation of symptoms, onset, and course of illness along with personal, past, and family histories. MSE can help gauge the present status of illness presentation, temporally, in the patient.
- ii. Physical examination: to help rule out any medical problems that could be causing overlapping or similar symptoms and check for any medical complications, if any.
- iii. Screening tests: to rule out differential diagnoses and screen for possible symptomatology that could hint towards the psychosis presentation.
- iv. Diagnostic criteria for schizophrenia: a mental health professional may use the criteria in the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) to confirm the illness presentation.

Clinical psychological assessment is also carried out for patients with schizophrenia to understand their motivations and presentation of the illness. These tests generally include projective testing techniques such as the Rorschach Inkblot Test, Thematic Apperception Test, and Drawing tests. Apart from these, several other rating scales can be used to confirm the presence of symptoms of the illness for a surer evaluation. Some of them being the following (Kumari et al., 2017):

1. *Positive and Negative Syndrome Scale (PANSS)*: Often referred to as the "gold standard" for measuring treatment progress. The PANSS scale involves an interview of about 30-40 minutes taken by the clinician, interviewing the caregivers, and reporting their symptoms (positive and negative).
2. *SANS and SAPS Tests*: SANS (Scale for the Assessment of Negative Symptoms) and SAPS (Scale for the Assessment of Positive Symptoms) check for the presence and effect of positive and negative symptoms in patients. It measures 25 negative symptoms of schizophrenia. SAPS test is a Scale for the assessment of 34 positive symptoms.

3. *Brief Psychiatric Rating Scale (BPRS)*: It is one of the most typical tests psychiatrists use to check the severity of schizophrenia using a checklist of 18 symptoms or behaviors.
4. *Clinical Global Impression-Schizophrenia (CGI-SCH)*: This test has been adapted from the more general Clinical Global Impression score, which is used to diagnose other psychiatric illnesses. Like the PANSS, this scale also assesses the progress of treatment but, contrastingly, can be used with a group of patients. The CGI-SCH measures two things: severity of schizophrenia and improvement on symptoms since the last check-up.

COURSE OF ILLNESS AND PROGNOSIS

With the severity of the illness, the course of the illness varies from patient to patient, depending on the frequency and intensity of symptom presentation, age of onset, severity of course, available emotional and social support, and treatment options. Though schizophrenia does not always end up in an excruciatingly debilitating condition, adverse effects of the illness indeed cripple most persons living with schizophrenia.

The course of the illness can be divided into four significant epochs: premorbid adjustment, the onset of illness, middle course, and late course. The premorbid adjustment refers to symptoms that appear prior to positive symptoms. Premorbid adjustment is manifested as poor social and academic adjustment, lack of social drive, decreased emotional responsiveness, social isolation, introversion, suspiciousness, or impulsive behavior among the cluster of symptoms, seen in about 25-50% of patients.

The onset of illness, the second epoch, typically refers to the onset of positive symptoms (i.e., hallucinations, delusions, and formal thought disorder). The onset of positive symptoms is insidious in about 50% of the patients, with the earliest signs showing several years before a full-blown episode of psychosis. This is usually indicative of a poor, intermediate course and poor prognosis. In cases where onset is relatively sudden or acute, in patients with typical development, the outcome and prognosis are generally more robust and positive. Childhood onset of the illness is a poor prognostic indicator for the illness.

The third epoch or middle course of illness has two sub epochs: the first has multiple exacerbations of positive symptoms and the second sub epoch (plateau phase), brings some stabilisation for the patients and a decrease in symptom exacerbations. Studies have shown that deterioration seen in the course of illness happens in the first or middle of the course rather than the remaining in the illness (Emsley et al., 2013). However, it must have adhered to the fact that schizophrenia remains a severe social and occupational burden regardless of the degree of recovery.

In the late course of illness (last epoch), there is a tendency for the intensity of positive symptoms to diminish. Improvement of social and occupational competence is seen in many patients with long-term impairments. Though the illness is less disruptive and easier to manage, it remains challenging to overcome the effects of years of dysfunction from the past. The years of life lost to disability and thus, impacting the quality of life is a loss that cannot be compensated for. Conclusively, in addition to the poor recovery outcomes, people with schizophrenia have a significantly reduced life expectancy and high excess mortality

compared to healthy controls (Charlson et al., 2016). Approximately 55% of patients with schizophrenia have moderately good outcomes, and 45% have severe outcomes (Häfner, 2015). It is promising to rely on these results for two reasons: the sample selection was representative, and that effective treatments with moderate and long-term benefits were administered.

TREATMENT MODALITIES

Schizophrenia is not curable but treatable and manageable with medication and psychological, behavioral interventions when diagnosed early and treated without a break. Treatment modalities of schizophrenia typically include psychotropic drugs to reduce the symptoms, psychosocial interventions, cognitive-behavioral therapy, which can help "train" patient social skills once symptoms are reduced. Psychopharmacological interventions are dominant in the public health system.

Recent evidence highlights that patients undergoing regular psychosocial interventions comply better with medication and have fewer relapses and hospitalizations (Chien et al., 2013; Loh et al., 2017; Saha et al., 2020). A stronger alliance with a patient with schizophrenia may offer a reliable source of information about schizophrenia and empathy, encouragement, and hope. Social networks and family member support have also been shown to be helpful.

Recent clinical researches have increasingly indicated significant improvement in patients' long-term health outcomes with community-based psychosocial interventions (Asher et al., 2017). Recent research and systematic reviews indicate that both psychiatric and psychosocial treatment offered early can improve their prognosis and even help prevent their worsening severity (Bellack, 2001; Chien et al., 2013).

Evidence suggests that health outcomes may be related to the time interval between the initial detection of schizophrenia and the initiation of psychotropic drug intervention. The timely diagnosis and treatment is associated with less severity of illnesses and positive prognosis. It confirms the importance of early screening of schizophrenia and the need for intensive therapeutic interventions, combining pharmacological and psychosocial treatments to ascertain positive health outcomes.

There is also considerable evidence suggesting the prophylactic use of psychotropic medication significantly reduces the relapse rate (Brissos et al., 2014). This potentially makes it possible to substantially reduce the load of inpatient care in favor of brief hospital stay, crisis intervention, and community-based treatment. It is well documented that an integrated approach including early identification and treatment of schizophrenia symptoms, a collaboration between patients and caregivers in managing treatment, family and social supports, and training in social skills improve the course and outcome of schizophrenia (especially symptoms, recurrence, social functioning, and quality of life).

TRADITIONAL MEDICINE AND HEALING PRACTICES

In many countries, schizophrenia is characterized as insanity or a mental problem due to possession by ghosts or evil spirits, thus approaching traditional healers for the treatment. A study conducted in Uganda, Egypt, found that a combination of modern psychiatry and traditional healing brings promising health outcomes (Abbo, 2011; Ibrahim Awaad, 2020). A recent study from India echoed similar findings, which complement existing primary health care services (Saha et al., 2021). Such approaches provide modern medicine access without compromising patients' religious and spiritual practices. A comprehensive review of scientific literature showed that several medicinal plants had been scientifically validated for the treatment of schizophrenia (Ahmed et al., 2014; Hoenders et al., 2018). Few studies from India have explored the role of Ayurveda (Indian medicine system) schizophrenia and found it complementary to psychotropic intervention (Agarwal et al., 2007; Ramu et al., 1992; Sarkar et al., 2012). Much robust evidence is required to explore the potential of traditional medicine to treat schizophrenia.

REHABILITATION AND REINTEGRATION

People living with schizophrenia require rehabilitation and reintegration to preserve a sense of physical wellness, mental, social, and economic well-being. Adequate daily exercise also forms part of a healthier daily routine and facilitates sleep patterns. For example, a study conducted by Saha and colleagues in India found that psychiatric rehabilitation of people living with chronic mental illness improves recovery (Saha et al., 2020).

Several approaches have been developed aiming at reducing the stigma associated with schizophrenia. Amongst major approaches, including social movement, mental health education, and educating people living with schizophrenia, the latter two approaches showed considerable reduction in the stigma (Corrigan et al., 2012; Stuart, 2016). These approaches must be included in an integrated approach to treat schizophrenia within the public health system.

CONCLUSION

The World Health Organization describes schizophrenia as one of the most severe and challenging psychiatric diseases. Although people with schizophrenia and affected people can lead a productive social life, limited numbers of people access appropriate and timely mental health care services. Evidence indicates a critical role of psychosocial intervention in recovery, rehabilitation & reintegration for delaying relapses. Additionally, traditional medicine and healing practices also play a crucial role in recovery; however, it needs more research in this area. In summary, schizophrenia still demands strong efforts to manage schizophrenia more effectively.

- practice concepts, 1379
- practicums, xvi, 1385, 1386, 1387, 1390, 1943
- precision medicine, 6353, 7433, 7434, 7435, 7436, 7437, 7438, 7439, 7442, 7443, 7444, 7450, 7451, 7452
- prediction, 2, 3, 92, 564, 1484, 1506, 1516, 1633, 1854, 2627, 2631, 2745, 2793, 2993, 3036, 3326, 3327, 3352, 3430, 3445, 3458, 3536, 3557, 3601, 3742, 3761, 3767, 3969, 4117, 4151, 4236, 4263, 4355, 4613, 4619, 4662, 4665, 4766, 4780, 5171, 5782, 5783, 5835, 6119, 6165, 6219, 6414, 6432, 6461, 6478, 6484, 6494, 6495, 6520, 6873, 6890, 7294, 7413, 7430, 7461, 7463, 7464, 7469, 7472, 7653, 7945
- preeclampsia, x, 579, 581, 621, 622, 623, 625, 626, 627, 628, 629, 630, 631, 3405
- pre-K, 229, 235, 236, 237
- premenopausal women, 3793, 7389, 7391
- pre-pubertal exposure, 814, 815
- preschool, xxxi, 201, 229, 230, 232, 233, 234, 235, 236, 237, 239, 262, 585, 591, 673, 675, 677, 685, 688, 690, 700, 1051, 1946, 2230, 3522, 3531, 3541, 3543, 3548, 3615, 3629, 3631, 3635, 4613, 4624, 4669, 4670, 4671, 4672, 4673, 4676, 4939, 5851, 6515, 7271
- preschool children, 585, 673, 675, 677, 688, 690, 700, 2230, 4624, 4671, 4672, 4676, 7271
- prescription painkillers, 7071
- presidential election, 4076, 4082, 4084
- preterm, vi, 155, 163, 164, 166, 172, 173, 177, 178, 615, 622, 630, 633, 634, 1134, 1140, 1143, 3513, 3533, 3536, 3537, 3540, 3585, 4126, 4895, 5345, 5359, 5366, 7240, 7248, 7503
- pretest-posttest design, 1357, 1393, 1394, 1462, 1468, 1489, 1983, 2005, 2018, 2076, 2118, 2144, 2159, 2181, 2227, 2229, 2236, 2416
- prevention and mitigation actions, 6125, 6126
- prevention strategies, 402, 447, 475, 892, 3488, 3540, 3675, 3711, 3726, 3727, 5048, 5244, 6072, 6090, 6400, 6402, 6403, 6774, 6883, 7040, 7140, 7216, 7220, 7288, 7568, 7862, 7889
- preventive and mandatory isolation, 6993, 6999, 7010
- preventive care, 180, 181, 184, 190, 204, 628, 878, 1017, 1187, 3820, 4975, 4986
- price liberalisation, 3999, 4044, 4067
- primary (main) bronchus, 6469
- primary angitis of the nervous system, 3003
- primary CNS vasculitis, 2470, 2485, 2612, 2859, 2991, 2992, 2993, 3002, 3003, 3011, 3012, 3013, 3015, 3016, 3017, 3042, 3131
- primary health care, 144, 191, 304, 424, 455, 824, 4628, 5700, 5752, 5865, 5869, 5870, 5873, 5913, 7341, 7343, 7344, 7348, 7499, 7506, 7696, 7802, 7883, 7969
- primary systemic vasculitis, 2450, 2475, 2489, 2504, 2514, 2617, 2648, 2738, 2740, 2856, 2858, 2871, 2892, 2902, 2926, 2949, 2991, 2995, 3071, 3137, 3138, 3139, 3140, 3141, 3150
- private wells, 818, 3510, 3587, 3588, 3589, 3590, 3591, 3594, 3595, 3596, 3600, 3601, 5006, 5013, 5014, 5015, 5016
- privatisation, 3971, 3976, 3980, 3983, 3985, 3999, 4005, 4021, 4057, 4065, 4066, 4067, 4088, 4091, 4100, 4107, 4109, 4116
- probiotic(s), xxix, 4145, 4153, 4154, 4159, 4160, 4162, 4165, 4166, 4169, 4170, 4174, 4175, 4176, 4177, 4178, 4179, 4180, 4181, 4183, 4184, 4186, 4187, 4188, 4189, 4190, 4191, 4192, 4193, 4194, 4195, 4197, 4198, 4202, 4229, 4230, 4233, 4234, 4246, 4252, 4254, 4256, 4263, 4266, 4273, 4274, 4277, 4288, 4290, 4291, 4293, 4294, 4296, 4297, 4298, 4299, 4300, 4301, 4317, 4339, 4340, 4341, 4343, 4345, 4346, 4347, 4348, 4349, 4350, 4351, 4353, 4354, 4362, 4363, 4364, 4366, 4367, 4368, 4369, 4370, 4373, 4375, 4376, 4377, 4378, 4380, 4381, 4382, 4383, 4388, 4389, 4391, 4394, 4397,

- 4398, 4399, 4400, 4401, 4402, 4403, 4405, 7401, 7403
- problem-based gaming, 6163, 6164, 6167, 6170
- productive relationships, 1377, 1380, 1382
- productivity, 65, 76, 126, 597, 599, 806, 850, 853, 1099, 1212, 1357, 1432, 1476, 1561, 1611, 1613, 1840, 1857, 1873, 1889, 1904, 1905, 2037, 2210, 3150, 3457, 3463, 3464, 3475, 3511, 3529, 3674, 3750, 3787, 3788, 3789, 3790, 3872, 3974, 3988, 3989, 3996, 4006, 4090, 4110, 4118, 4121, 4132, 4214, 4253, 4284, 4314, 4392, 4395, 4396, 4401, 4407, 4874, 4966, 5839, 5842, 5849, 5850, 5862, 5873, 6002, 6311, 6707, 6953, 6966, 6969, 7126, 7216, 7643, 7644, 7652, 7658, 7759, 7847, 7929
- professional and academic education, 1304
- professional training, 328, 348, 1577, 2325, 2362, 4611, 4632, 5698, 7809
- program content, 330, 331, 332, 341, 343, 347, 349, 1491, 1497, 1498, 1499, 1502, 1509, 1512, 1514, 1515, 1516, 1517, 1520, 1521, 1525, 1527, 1528, 1529, 1530, 1531, 1532, 1534, 1537, 1538, 4699, 4701, 4702, 4703, 4704, 4705, 4706, 4707, 4711, 4713, 4714, 4715, 4716, 4718, 4719, 4723, 4727, 4730, 4731, 4739, 4740, 4741, 4742, 4743, 4744, 4745, 4746, 4749, 4751, 4752, 4753, 4755, 4756, 4757, 4763, 4764, 4765, 4766, 4769, 4773, 4775, 4776, 4777, 4779, 4780, 4788, 4789, 4791, 4794, 4795, 4796
- program effectiveness, 330, 1396, 1420, 1497, 1498, 1500, 1502, 1525, 1528, 1529, 1530, 1531, 1533, 1534, 1537, 1538, 1562, 1733, 1750, 1764, 1841, 1944, 2121, 2123, 2182, 2362, 4606, 4699, 4701, 4702, 4703, 4705, 4706, 4707, 4711, 4714, 4715, 4717, 4718, 4719, 4720, 4739, 4740, 4741, 4742, 4744, 4745, 4746, 4751, 4752, 4753, 4754, 4755, 4756, 4757, 4763, 4764, 4765, 4766, 4768, 4796, 5107
- program evaluation, 330, 341, 372, 629, 1363, 1422, 1440, 1488, 1776, 2123, 2133, 2158, 2162, 2233, 2326, 2358, 2359, 2362, 2371, 2372, 2413, 3645, 4701, 4703, 4740, 4751, 4752, 4757, 4796, 7087, 7091
- program implementer(s), 330, 335, 341, 349, 353, 1148, 1497, 1499, 1506, 1729, 2105, 2158, 2162, 2170, 2362, 2372, 2417, 4602, 4606, 4607, 4699, 4702, 4703, 4704, 4705, 4706, 4707, 4711, 4713, 4714, 4715, 4716, 4717, 4718, 4719, 4720, 4722, 4725, 4740, 4750, 4751, 4752, 4753, 4754, 4755, 4756, 4757, 4758, 4759, 4772, 4776, 4780, 4781, 4782, 4788, 4789, 4790, 4794, 4795, 4879
- program instructors, 331, 336, 347, 1502, 1512, 1514, 1516, 1521, 1525, 1527, 1529, 1530, 1531, 1532, 1534, 1537, 1538, 4727, 4730, 4739, 4740, 4741, 4742, 4743, 4744, 4745, 4746, 4765, 4767, 4776, 4796
- program quality, 327, 330, 331, 332, 335, 336, 339, 341, 343, 347, 348, 349, 1512, 1520, 1947, 2123, 2148, 2182, 4723, 4727, 4728, 4730, 4731, 4732, 4753, 4755, 4761, 4764, 4768, 4775, 4796
- programmed cell death (PCD), 3863, 3864, 3867, 3868, 3869, 3872, 3873, 3874, 3875, 3876, 3877, 3878, 3879, 3899, 3904, 3907, 4262, 6607
- programmed death 1 (PD-1), 3077
- pro-inflammatory cytokines, 2519, 2579, 2642, 2865, 6392, 6393, 6445, 6480, 6488, 6606, 6607, 6636
- pro-inflammatory mediators, 2532, 6472
- project flame, 1942, 1953
